At the same time, proposals for new operative business strategies are being launched which explicitly incorporate characteristics of online consumption modes, such as 'collective knowledge' production (e.g., Wikipedia) or 'crowdsourcing' (e.g., www.sellaband.com). Marketing specialists have recognized one particularly salient trait of Internet communication: the possibility to create 'word-of-mouth' effects in an online context, thereby generating a certain 'buzz' which is both perceived as authentic valorization by peers and yet can have the scale of mass advertising. This has been labeled Electronic Word-of-Mouth (eWOM). Noninstitutionalized platforms for 'user-generated content' such as cultural blogs can consequently be targeted to have marketing messages distributed through bottom-up processes.

A third strand of research addresses the symbolic production of culture on the Internet. One emancipatory manifestation of such work – emphasizing how fans and other 'common' (prod)users – negotiate the meaning attributed to popular culture – is found within the paradigm of cultural studies. Most of this work concerns ethnographic accounts that elucidate the place of audiences in the 'convergence culture' (Jenkins, 2006), a constellation in which media are understood to fulfill increasingly similar functions for ever more indistinct social groups. As such, often social inequalities in terms of education, age, or gender are argued to be no longer significant markers for taste and behavior, and notions of cultural authority are challenged. However, studies in cultural sociology argue that Bourdieu's (1984) concept of 'distinction' may have weakened due to the ascendance of more omnivorous cultural consumption patterns – that is combining highbrow and popular culture – but cannot be completely abandoned. Popular culture has also become more institutionalized over time, and many of such off-line configurations tend to be reproduced in online contexts.

Material Production and Distribution

Most discussion on how Internet affects the world of arts and culture apparently concerns the way cultural products are produced and distributed. Illegal downloading is a major concern in the cultural industry: all cultural goods that can be electronically copied (music, film, photographs, books) are increasingly being disseminated without permission of the original cultural producers who consequently suffer loss of revenue (Levine, 2012). Yet also legal ways in which products find their way to audiences (via web stores or intermediary sites such as YouTube or Flickr) affect how the cultural industry as mediators are being sidetracked. Although the disruption of traditional business models in the cultural industries has prompted many observers to signal the start of a completely new era – for the worse or for the better – in many ways there is also continuation of old discussions.

In mid-twentieth century, the introduction of 'reproduction' of recorded images (film, television) and sounds (music), aroused strong debates on what constitutes 'art' and to what extent cultural products could be 'commodified' in an almost industrial way (e.g., Frankfurter Schule). Despite reproducible products becoming key ingredients in the diets of many cultural audiences in the second half of the century – and thus losing most of their controversy – criticism never completely disappeared. While many sociological and media/cultural economic studies pursue objective analysis of production practices and their implications, normative perceptions on cultural value or the functioning of the industry are still widely spread. Examples of such expressions are for instance found in critiques on how book publishing threatens standards of literary culture, or in the political economist's concerns that the corporations involved in cultural production reduce the variety of opinions and tastes through their shaping of news, entertainment, and other media expressions.

These discussions resonate in theoretical publications on cultural production in the digital age, which tend to take two competing perspectives. Both of them, however, appear to draw on three underlying argumentative dimensions: economic, artistic, and moral considerations. Among Internet's criticasters, a first group emphasizes the destructive effects that Internet-related practices have on the existing cultural industries. Their main argument is that the 'free riding' behavior, which Internet provokes will decrease incomes such that it will ultimately drive cultural producers out of business (e.g., Levine, 2012). This view is countered, however, by various theorists who argue that Internet also offers new opportunities for business as producers can take advantage of 'collective wisdom' production and user-generated content to gain more insight in consumer demands (e.g., Tapscott and Williams, 2008).

A second type of arguments concerns the 'quality' of the output. Antagonists mainly lament the decline of artistic – but also journalistic – quality and diversity in content that Internet allegedly induces. In their view, 'user-generated content' does not meet the standards of institutionally produced content, due to the absence of professional gatekeepers, which would degrade the available supply (e.g., Keen, 2007). Again, opposite viewpoints are taken. Particularly in the domain of news production, some argue that 'user-generated' content increases diversity of voice, and as such contributes to a multiform society. In addition, Chris Anderson (2006) in his book *The Long Tail* points at increasing diversity at the aggregate level. Centralizing the storage and searchability of cultural products in an online context (e.g., a web store like Amazon) enables consumers to discover products out of the mainstream, and, consequently, producers to exploit niche markets, which were not profitable before the digital age. He argues that this may very well lead to the end of the 'blockbuster economy.'

Finally, there is a third group of scholars that stresses more moral and ethical aspects of Internet, particularly the issue of copyright and ownership of cultural content. Violation of copyright is one of the main concerns of the industry with regards to Internet distribution of culture – and this obviously includes also the creators of culture themselves (the artists). Besides the loss of economic revenue, infinite reproduction and unofficial distribution via new media also invokes a moral contemplation of the value of 'creation.' Artists who take considerable pains in creating new works of art see themselves confronted with audiences who increasingly expect free and instant satisfaction of their individual cultural wants – disregarding the artists' investments. The advent of 'user-generated content' fueled this debate on copyrights, as we find also theorists who argue that taking existing content to recreate and remix cultural expressions is not very different from traditional artists finding inspiration in folk tales or using samples and quotes (Lessig, 2008). On the most fundamental level, however, copyright discussions address the question whom the current system truly benefits most – and whether that is changing: the media conglomerates that do most investments, the artists who are the source, and/or the art that seeks innovation.

Many of these issues regarding production and distribution currently remain unresolved, as empirical evidence is often lacking or hard to find (Curran et al., 2012: 69ff). For instance, there is, as yet, no clear evidence that The Long Tail has indeed become such profitable market niche that it inflicts death on the blockbuster. And while illegal downloading in all likelihood affects the cultural industries, these industries have also been slow to innovate: record companies have been retailing their back catalog for years (via the cd); film companies have increasingly centered their production around formulaistic high-spectacle blockbusters. Meanwhile many new business models – such as crowdsourcing models or 'value-based pricing models' – are still too young for definite conclusions (Wikström, 2009). And lastly the copyright wars are not yet decided – despite new initiatives such as 'blanket protection' in which the rights to distribute products are granted to Internet service providers in exchange for payment – being underway (Levine, 2012).

Meanwhile new media are increasingly applied within the marketing of cultural products. In the film industry, trailers of new movies are increasingly disseminated via the larger film blogs that in many ways have taken over the dominance of trade journals in breaking news and reporting on the movie scene. For the book industry, Thompson (2010: 243ff) shows how author tours and print advertising are increasingly being replaced by online advertisements and building word-of-mouth via the blogosphere. Getting positive reviews are not the aim. Instead, publishers target a relatively small group of influential bloggers in order to create a certain 'buzz,' which can translate in off-line demand.

Symbolic Production

Consensus on what cultural manifestations are artistically valuable or important – in other words, (are) legitimate – has traditionally been reached through highly hierarchical systems. Within thematically organized domains or fields, institutions operated through agreements on how production and distribution practices should be performed (Bourdieu, 1993). Both institutions and individual agents within these institutions nevertheless compete for cultural authority through securing and expanding their influence in the field, as higher levels of assigned expertise translate in more status. At the same time, the agency of audiences – when contributing to the process of legitimation – has been more of a receptive nature than a productive one.

Yet value attribution to cultural products is not hierarchical per definition. Legitimation should be seen as a social process, since institutional agents rely heavily on having an audience that accepts their selections and evaluations, or in other words puts 'belief' in them (Bourdieu, 1993). In the traditional system, print media such as newspapers, opinion magazines, and academic journals served as outlets for institutional agents, stressing the top-down process of legitimation by its unidirectional character from producer to consumer. The reason for this was twofold: (1) the selection of persons who could enter the field was confined to those showing the ideas already dominant in the field and (2) the ideas of these agents working in the media field on what makes legitimate culture resembled the ideas of their audiences since they were largely recruited from the same social ranks (Bourdieu, 1993).

The arrival of the Internet has led to less hierarchical systems of classifying information – among which evaluations of culture – due to its specific characteristics, as is theorized by Verboord (2010, 2013). The open nature of the Internet has enabled cultural audiences without institutional ties to engage in discussions of quality or value beyond merely reacting to professional critics. Not only do audiences have the means to be faster to evaluate (as publications of traditional print media are often still slowed down by editorial checks and publishers' time to process), they also publish outside traditional institutional settings. Particularly within popular culture, discussion forums and consumer review sites circumvent professional critics and authorities. Often, evaluating culture is also more explicitly linked to the purchasing of cultural goods (e.g., web stores such as Amazon) and is rescaled from a few extensive, in-depth evaluations to a large number of short, sometimes ill-written, biased, or even invalid comments (cf David and Pinch, 2006). Symbolic production in the cultural field has thus been restructured in the sense that dispersion of audience attention, larger diversity of voice, uneven quality in writing and argumentation has made it harder for cultural critics to solidify their authority. In this fast changing media landscape, media outlets, and the critics therein, have more and more difficulty to stay connected to specific audience groups. This declining homology between media and audiences is particularly salient on the Internet, which puts considerable pressure on the legitimacy of critics and related institutional agents. This does not mean expertise is no longer important, however. The empirical results of Verboord (2010) demonstrate that expert critics are still valued higher than online critics. Similarly, studies in computer-mediated communication show that textual properties and communication tactics are highly important to be considered as prominent and 'useful' reviews (e.g., Otterbacher, 2011). Traits associated with professionalism such as correct spelling and high levels of argument

density are thus used to filter out credible information in the enormous online supply. Still, the ascendance of peer-produced content challenges the hierarchical model of cultural evaluation, though it remains in use, but particularly stimulates the use of popular aesthetics as the standard form of evaluative discourse (Verboord, 2013).

It remains to be seen if symbolic production has become more democratic and multiform in the digital age. Traditionally, cultural genres with more social status tend to show more inequalities in terms of gender, ethnicity, and social class. An exploratory analysis of the fiction book output in 1 month in the United States showed that female authors generally were more often reviewed on Amazon and social network Goodreads than male authors, whereas print media showed no significant difference (Verboord, 2011). This result may, however, be typical for the book market in which women form a large part of the readership.

Audiences

Cultural Participation

Much of the reduction in control that cultural producers used to have in producing and disseminating content has accrued to audiences. Provided that one has the access and the digital skills to go online, it is often easier, faster, and cheaper to purchase products and tickets, find information, contact like-minded persons, share opinions and emotions on experiences, etc. in this digital environment. Representative studies into the way cultural participations are affected by online mediation are rare, however. One of the few attempts to map cultural participation through new and traditional media is conducted in 2009 at the Netherlands Institute for Social Research for a representative sample of the Dutch population, aged 18 years and older (Sonck and De Haan, 2012). Contrasting popular culture (pop music, film) and traditional culture (theater, visual arts, cultural heritage, classical music) in both receptive and more active modes of participation, they show huge discrepancies across activities and cultural forms. Overall, old media are still used more often than new media. Even among the youngest age group – 18–34 – new media have a complementary rather than a substitutional role.

In absolute terms, Internet is most often used for finding information: more than 40% of the population has ever looked for information on pop music, film, or theater. For the other art forms, this percentage lies between 10 and 20%. About a quarter of the population buys tickets and/or recordings of pop music or film via the Internet. Still, only with regards to pop concert tickets, online buying has actually surpassed off-line buying. Purchasing highbrow culture via the Internet is mainly restricted to buying theater tickets (34% vs 36% offline). Actual (mediatized and receptive) cultural participation – viewing and/or listening to objects and recordings – is predominantly done via audiovisual media. Online participation amounts to almost 20% for all cultural forms, except classical music (only 5%) and pop music (almost 30%). Despite web2.0 tools becoming increasingly available, active forms of participation are not widely spread. Creating and sharing cultural content were established for a third of the Dutch, but this includes photographs and diary fragments which may be uploaded just for friends. Only 5% reported to ever have posted messages on arts and culture.

These online participation trends – though perhaps partly superseded by advancing ICTs and media logics – reveal the contextual imperative of the social shaping of technology. Online participation variably relates to particular issues such as scarcity (ticket purchase for performances), searchability (information), replicability (music files), or archivability (cultural heritage, visual arts). Contrary to what some Internet gospellers state, simply having the opportunity to use the Internet for a particular purpose is clearly not enough to propel such usage. Dependent on their skills, attitudes, and incentives, audiences pursue applications that enable them to efficiently find desired gratifications and affordances. Which online services come into vogue is difficult to predict. Successful online services seem to originate more often from outside traditional cultural production and benefit particularly popular culture. Although producers of highbrow products similarly need to relate to their clientele, this audience group is generally smaller, older, and more aligned to institutionally rather than peer-produced expertise. As a result, many of these producers still take the tradition as the point of reference, such as virtual museums, which are principally created to make collections and associated documentations more accessible, and secondly want to provide an entertaining and educational experience (Styliani et al., 2009).

Whereas such highbrow endeavors to reach out to audiences still command high levels of control, more popular culture has generated mostly interactive platforms where audiences are also enabled to become creators themselves. Video Web site YouTube is perhaps the most used and most famous form of such participatory culture: about half of its contents appears to be user-generated (Burgess and Green, 2009). The Web site exemplifies the notion of 'convergence culture' through its integration of different forms of media (television, film, music, photographs), but just as much in how culture is represented. Next to the wide circulation of original content produced in cultural industries' formats, many alternative versions of such materials are available in various degrees of editing, mixing-up, animation, imitation, etc. (Burgess and Green, 2009: pp. 42–43). Such media work of (semi-)amateurs consequently generates new, at times unclassifiable, genres outside of institutionalized settings. It is here where the cultural participation of audiences comes closest to reordering the status quo of cultural fields.

Cultural Information Regimes: Between Mass and Niche

The experiential nature of arts and culture together with the infinite variety of products implies that information on cultural products comprises a double-edged uncertainty. Since audiences can only evaluate products after consuming and experiencing them, they do not know whether they choose the 'right' product before acquisition. Consequently, producers do not know what products will become successful among audiences. Several information regimes are applied to reduce uncertainty. The most traditional, highbrow-oriented regime of cultural classification was already discussed in the previous section. On the Internet, market information

regimes, which inform producers and consumers on popularity, appear more important, however. It is almost standard practice on the web to inform Web site visitors about the popularity of the Web site itself, particular texts on that site (e.g., by letting visitors assess the usability, or give a Facebook like), or products on the site (e.g., book sales on Amazon.com; number of previous downloads).

The potential power of online-disseminated market information was demonstrated in a web-based experiment by Salganik and Watts (2008) that created parallel online universes in which the same (relatively unknown) pop songs were attributed different popularity scores by the researchers. Once consumers could start to listen to the song corpus and download their preferred tracks, the demand curve developed consistently in favor of those songs which had the largest (manipulated) download scores from the start. Yet if the same songs in a different online universe had been flagged as not been downloaded a lot, demand did not grow hard. This result underscores the more general observation that although Internet has increased the supply of media content to almost infinite proportions, demand appears to be highly concentrated because information overload is an impetus to use filters such as popularity markers.

Despite these results, empirical studies suggest that interpersonal ties still prevail above Internet sources when looking for cultural information (Kayahara and Wellman, 2007). While Internet is frequently used to find detailed information on particular products or events, recommendations on which artists or products to look for in the first place often still comes from the personal off-line network. What is more, despite technology use to find new music being highly diversified, it does not seem to help more people to become opinion leaders in their social circles nor online (Tepper and Hargittai, 2009). In a similar vein, participation in social network sites mainly follows from off-line contacts or interests, making it easier to connect to like-minded persons, but not necessarily leading to new friendships (Baym and Ledbetter, 2009). Still, there is increasing evidence that social media are reshaping cultural consumption practices (Dewan and Ramaprasad, 2012).

Discussing Culture: The Voice of the Consumers

Besides transforming systems at the societal level – such as access to cultural content and currency of information regimes – user-generated content is also strongly associated with new ways in which content is discussed and deliberated at the level of individual consumers of (popular) culture. Again, partly this follows from increased network opportunities. Internet has provided fans of popular culture with the means to (virtually) meet like-minded persons and share thoughts, interpretations, and evaluations on specific web forums. To be sure, the rise of fan culture has been underway since the breakthrough of popular culture in the 1960s, but from the start Internet proved to be an important facilitator of communication. Having started out as a domain for 'geek culture' in which mostly 'tech-savy' males propagated genres such as science fiction and alternative rock, it has widened substantially. Moreover, online fan culture has developed a voice, which exceeds in-crowd discussions on trivial content details. Particularly, Jenkins (2006) provides an account – within the broader theoretical framework of media convergence – of how new media enable fans to influence practices of corporate producers. Fans contribute to the producers' deeper understanding of how their work is interpreted and evaluated, and, ultimately, how program loyalty can be achieved. Interactive television formats in which viewers can for instance vote in talent shows accommodate this connection to the fan base. At the same time, some content fans create online may harm the interests of producers. Examples concern new stories on Harry Potter, which violate copyright laws or the emergence of 'spoiler' sites on which fans try to disclose television content before it is officially broadcasted. Although originally many of such practices are the work of small groups situated in relatively obscure online communities, grassroots convergence has empowered fans through collective intelligence. Interactivity first stirs the depths and intensity of communication within such communities. Subsequently, the content at stake – if it gains sufficient momentum – gets picked up by outlets higher in the media hierarchy, after which it may continue to be circulated until it reaches mainstream audiences. One important remark needs to be made: while such bottom-up processes do allow new products or creators to rise to stardom (e.g., rock band Arctic Monkeys via MySpace), most participations reported in these fan studies still concern popular culture produced in the cultural industries. Moreover, this is in line with results from other studies into participatory culture such as YouTube: user-created content augments diversity yet audience attention is most drawn by what originated from traditional media (Burgess and Green, 2009).

Prospects

Despite the rapidly growing literature on new media and Internet, research which focuses on their impact on arts and culture remains relatively limited and scattered across disciplines. Internet's novelty, its omnipresence and the fast pace at which it penetrated Western society not only spurred a great variety of perspectives, but also stimulated theory to regularly develop without empirical falsification.

More empirical evidence for theorized effects is needed. Part of such empirical underpinning would entail employment of multiple methods and cross-disciplinary perspectives. For instance, studies into online fan culture remain persistently qualitative in nature – thereby preventing generalization of findings. At the same time, research into effects of online reviews largely relies on quantitative measures, often based on student experiments.

Connecting different research perspectives thus appears to be one of the major challenges for the study of arts and culture in the digital age. Such interconnections help to better understand some of the paradoxes that emerge from the current literature. For instance, how the creation of user-generated content has reversed many cultural flows from top-down to bottom-up, but at the same time most cultural content which is circulated online still springs from the cultural industries (either in original or remixed versions) and only a limited number of Internet persons can actually be called 'produsers.'

Or the observation that the Internet facilitates the convergence of media, cultural genres, and even consumption and production practices, yet what is actually consumed and produced is subject to increasingly larger fragmentation and individualization. Also, the role of social network sites (e.g., Facebook) in taste formation, the use of technology to recommend consumers mainly cultural products very similar to what they purchased before, and the future of physical cultural outlets in an increasingly digitalizing world are important themes for future research.

Internet and Privacy

Andreas Busch, Georg-August-Universität Göttingen, Göttingen, Germany

Abstract

The issue of informational privacy has grown in political prominence and importance as use of the Internet has spread around the globe. Economic interests base business models on users' indirect payment with personal data; criminals engage in fraudulous 'identity theft'; and private and public sector surveillance is conducted in order to increase security. But attempts at protecting privacy through regulation on both national and international levels face substantial difficulties which relate to both technical and political causes.

Introduction

The Internet has become an indispensable feature of everyday life in the first decade of the third millennium. No longer confined in use to experts but user-friendly enough to require little training, the Internet is now available not only to citizens in developed countries (where around 80% now have access), but will be to almost 3 billion people around the world by the end of 2014 (40% globally; 32% in developing countries). The contribution to economic growth and dynamism undoubtedly counts among the beneficial consequences of this development. But worries about the negative effects that may accompany this have also emerged, for in a world where users are continuously 'online,' privacy can be endangered if their every move and request can be traced, stored, searched, and potentially forever replicated. Threats to privacy can come from various directions: well- and ill-intentioned governments, eager to learn about their citizens' lives, or focused on protecting them from terrorist threats count among them, but so do commercial enterprises interested in turning personal data into revenue streams or wanting to maximize service to their customers. Whether firms like *Facebook* or *Google* – whose customers number in the hundreds of millions – use their accumulated knowledge in the right way has thus become a subject of debate in recent years. Most discussion about threats to privacy today has to do with the connectedness and linkage of personal or person-related data through the Internet. Both public and private sector actors have responded to these worries with attempts at (self-)regulation, on the national and on the international level. However, much of this field remains contested and little has been achieved in terms of encompassing goals and standards for such regulation. Since June 2013, privacy has also come on the political agenda in many countries after revelations about systematic snooping by security agencies such as the National Security Agency (NSA) in the United States, Government Communications Headquarters (GCHQ) in the United Kingdom, and Bundesnachrichtendienst (BND) in Germany emerged.

Privacy and Technology

While privacy is a basic human need and is constitutive for the individual, it remains difficult to describe and define. Across societies, the desire and need for privacy has varied historically (Moore, 1984), and in the process of modernization, demand for privacy has tended to grow in order to balance societal intrusions resulting from developments such as greater population density. In the theoretical debate, however, no generally accepted definition has so far emerged. More than 45 years ago, Alan Westin (1967, p. 7) wrote in his seminal study on the subject: "Few values so fundamental to society as privacy have been left so undefined in social theory or have been the subject of such vague and confused writing by social scientists." A recent comprehensive work in the area makes basically the same point when it states: "Privacy, however, is a concept in disarray. Nobody can articulate what it means." (Solove, 2008, p. 1). The main reason for this lies in the fact that privacy is defined negatively as an absence of intrusion; such intrusions, however, can come from many directions and vary in type and subjectively perceived intensity, hence leading to different priorities for their avoidance.

Discussions about privacy and its intrusions have almost always been linked to technological developments. Already in the late nineteenth century, the emergence of 'instantaneous photographs' was seen as invading privacy, prompting calls for a right "to be let alone" (Warren/Brandeis, 1890). In the 1920s, the tapping of telephone lines for purposes of law enforcement led to debates resulting in stringent regulation and reporting requirements for such actions. In the 1960s and 1970s, plans for comprehensive 'data banks' and 'national data centers' containing electronic records of every citizen prompted debates about the relative merits of optimizing the state's social planning versus protecting privacy (Miller, 1971) and stopped most of these developments. From the 1990s onward, the proliferation of CCTV systems led to discussions about a 'surveillance society,' in which there was "no place to hide" (O'Harrow, 2006), as every move could be watched and recorded. After the terrorist attacks in the United States on 11 September 2001, plans emerged to put technology to the service of antiterrorism, but technocratic dreams of 'Total Information Awareness' through 'data mining' of all available public and private sector information sources turned out to be neither feasible nor desirable (National Research Council, 2008).

In the context of technology, privacy almost always means informational privacy and thus focuses on a specific part of the debate about privacy (Rössler, 2005). Analyzing the relationship between the Internet and privacy thus requires looking at the competing interests over person-related data as well as at the

attempts to set rules about their creation, proliferation, storage, and use.

Internet Use and Personal Data

Development of Internet Usage

Usage of the Internet has made the transition from expert domain to everyday use in the last two decades. Originally developed by military and academic experts to provide a safe means of communications even in the event of a nuclear war, and used first to link up leading research centers, the 'Internet' is actually a system of various connected computer networks that function by adhering to common technical protocols. Hiding the underlying complexity from the user and making a vast network of billions of nodes easily maneuverable through naming systems and graphical interfaces has been a condition for its exploding usage as well as for its commercial success, with the latter providing the funds for the Internet's ever-increasing capacity.

Internet use has increased dramatically since the turn of the century. In 2000, the percentage of individuals using the Internet was between 20% and 40% in developed countries (France: 14%; UK: 27%; Germany and Japan: 30%; US: 43%), and the global number was at a mere 6.5%. By 2013, numbers had shot up to around 85% in the first group (US: 84%; France: 82%; Japan: 86%; UK: 90%; Germany: 84%), while the global number had increased sixfold to 40% ('ITU database' http://www.itu.int/). This massive growth was unexpected even by experts who did not foresee the explosive development of mobile Internet access at broadband speeds which helped in particular to connect citizens of developing countries to the Internet in only a few years. As a result, an estimated 2.7 billion people around the globe had access to and used the Internet in 2013 (International Telecommunication Union, 2013, p. 1).

While these impressive growth figures have contributed substantially to development goals in developing countries (where they have, e.g., helped to introduce mobile banking and to spread public health and education information), it is in the developed countries that commercial activity initiated by and through the Internet is strongest. Electronic commerce has been a growth engine in many developed economies, contributing further to a shift toward a knowledge and information-based economy that has been under way at least since the 1960s (Machlup, 1962). But the Internet has also triggered the emergence and meteoric rise of new corporate stars such as Google (search engine) and Facebook (social media). These firms (which are used here as illustration for many others that are similar) build their business models on the use and processing of person-related data, for they charge no fees for their services from their customers. Instead, customers pay indirectly with their personal data which firms – through sophisticated mechanisms – monitor, store, and then use to create profiles. These profiles in turn allow them to sell advertisements which are highly targeted to the user's sociodemographic characteristics, thus increasing their success rate and extracting premium prices from advertisers.

How much successful firms like Google and Facebook depend on this business model is evident from business data submitted in companies' quarterly reports to the US Securities and Exchange Commission (SEC): in the first half of 2012, advertising revenues made up 96% of Google's overall revenues; and Facebook (which reported 955 million 'monthly active users' and 552 million 'daily active users') earned 84% of its total revenue from advertising ('SEC,' http://www.sec.gov/). In short, these firms would not be commercially viable without advertising revenues from personal data.

User Demand for Internet Privacy

In their corporate mission statements firms like Google and Facebook neither mention the commercial use they make of person-related data nor their dependency on them. They describe their mission as, respectively, "to organize the world's information and make it universally accessible and useful" (Google) and "to make the world more open and connected" (Facebook).

Being more open about their actual business models might cause worries among the hundreds of millions of customers who use their services on a daily basis. Google, for example, answers between four and five billion search questions per day; it logs and keeps all search queries as well as users' IP addresses, in addition to 'cookies' (small data files that track a user's Web browsing), and (where applicable) location information ('Google,' https://www.google.com/policies/privacy/). Thus the firm obtains a lot of person-related data which it may combine with information that users turn over voluntarily when registering for a user account with the firm, such as name, e-mail address as well as telephone and credit card numbers or device identifiers. Given that the company's market share is 95% of the search engine market in some European countries, this means that users may have few alternatives to using these services.

According to surveys, users value their privacy highly and are concerned about the protection of their personal data on the Internet. General worries about privacy and data protection predate the advent of the Internet, but the availability of online electronic commerce means most consumers were only confronted concretely with the issue of being asked to enter personal data online in the late 1990s. In an internationally comparative survey commissioned by IBM, 80% of respondents in the US, 68% in the UK, and 79% in Germany agreed with the statement "Consumers have lost all control over how personal information is collected and used by companies" (Louis Harris & Associates, 1999, p. 22). Data from the Eurobarometer survey show that the level of 'concern' about data privacy has changed little since the early 1990s, with 68% expressing it in 2008 and 66% in 1991 – the worries are thus not primarily triggered by the Internet. Underlying this stable trend, however, are substantial differences in attitudes between countries: Austria and Germany top the field with a rising trend and 86% expressing concern, while at the bottom of the list are Finland and the Netherlands with 35% and 32% respectively and (in the latter case) a declining trend. With respect to the Internet specifically, worries tend to be more pronounced: 82% of EU respondents thought that data transmission over the Internet was not sufficiently secure, with some variation across countries but little across sociodemographic differences (Gallup Europe/European Commission, 2008). On the other hand, the disclosure of personal information is seen by many

as a part of modern life. They do disclose such information for the purposes of online services and online shopping, but 70% of Europeans are concerned that their personal data held by companies may be used for a purpose other than for which it was collected (European Commission/TNS Opinion and Social, 2011).

In sum, a strong preference for privacy, and worries about safety of personal data submitted online do not prevent citizens from using the Internet for online activity, but survey evidence indicates that they use it in a guarded way.

Problems of Crime, Security, and Surveillance on the Internet

The Internet was originally designed without central control in order to maximize the autonomy of heterogeneous networks working together. This not only conformed with military priorities of resilience in the case of a nuclear attack, it was also appropriate for the relatively small academic community in which users trusted each other; in addition it resonated with the libertarian impulses of the founding generation of engineers many of whom had links to the counterculture (Markoff, 2006). The result has been interpreted as a 'techno-utopian' attempt at self-regulation (Hofmann, 2012), a space almost completely free from formal boundaries and rules, in which the eventual emergence of problems with cybercrime is primarily an unforeseen consequence of past design decisions.

Cybercrime and Cybersecurity

What is now labeled 'cybercrime' has been emerging from the mid-1990s onward – when the originally wholly state-funded backbones were privatized and commercial use of the Internet took off – and taken various forms. The sending of unsolicited mass messages to initially many thousands, later millions of users advertising goods and services ('spam') was a first (and more annoying than dangerous) way of using the Internet for unintended activities. Initially done through e-mail (making use of the open nature of Internet e-mail servers), this activity was more recently primarily conducted through 'botnets' of PCs that had been taken over through the installation of malware. Such malware (viruses and 'trojans') can also be used to obtain passwords by logging and sending out users' keystrokes or to scan hard drives for files containing confidential information. Individual servers on the Internet, but also whole networks of firms or governments can be attacked through flooding them with IP packets (often from botnets), thus effectively shutting them down ('distributed denial of service'); and such attacks can be combined with attempts at extortion. Other forms of cybercrime include the sending of e-mail which claims to be from a user's bank or business partner, but which contain links redirecting responses to forged Web sites ('phishing') and the systematic use of personal data to impersonate other people for fraudulent purposes ('identity theft').

It is very difficult to obtain reliable information about the scale of the problem of cybercrime. Figures about its costs often make headlines – the British *Financial Services Authority*, e.g., estimated the cost of identity fraud to the UK economy at £1.7 billion per annum. This estimate, however, includes substantial amounts for lost or stolen credit cards, VAT losses, and even costs to state agencies for antifraud procedures. Furthermore, crime statistics do not routinely count whether IT was instrumental in committing a crime. Without more precisely targeted attempts to identify crimes committed online, a UK public inquiry concluded, "it is simply impossible to assess the scale of the problem" (House of Lords. Select Committee on the Constitution, 2009, vol. 1, pp. 15–16). As regards the inflated headline figures, it is clear that both in the public sector (law enforcement) and in the private sector (IT security firms) some actors clearly have an interest in pushing publicity of the issue.

Internet users, as far as survey evidence shows, have taken the dangers to heart and modified their behavior accordingly by trying to protect their privacy. 40% of Internet users in the EU are concerned about someone stealing or misusing their personal data; and 38% worry about the security of their online payments. Many of them have therefore changed their online behavior, and most of them try to avoid disclosing personal information online. When using the Internet for online banking or shopping, the two most common concerns are about someone taking or misusing personal data (mentioned by 40% of Internet users in the EU) and security of online payments (38%) (European Commission/TNS Opinion & Social, 2012, p. 4).

Both private and public sector actors have reacted to the threat and to the worries of users. IT security firms developed sophisticated tools to protect their customers' PCs from attacks through viruses and other malware and have built a substantial business around this; states have initiated international agreements (like the 2001 *Convention on Cybercrime* by the Council of Europe which contains common definitions and procedures on the subject as well as rules for international cooperation), passed national legislation, and set up competence centers to develop appropriate defenses.

Surveillance on the Internet

Security firms and state agencies thus work to protect users' privacy against illegitimate and foreign intrusion. But in order to do that, they collect lots of personal data which means we can look at the very same actors also with reference to the debate about surveillance. That debate focuses on how users on the Internet can be protected from the actions of legitimate firms and government agencies, and has been the subject of considerable social activism (Bennett, 2008). Firms' commercial interests were already mentioned above; government agencies, in turn, have an interest in using the Internet for the collection of person-related data for purposes of state and policy administration, social planning, law enforcement, national security, etc.

The concept of surveillance has been prominent in the sociological literature on personal and person-related information in recent years and has given rise to the academic field of *surveillance studies* (for an overview see Lyon, 2007; Ball et al., 2012). In this debate, the term surveillance has been defined very broadly as "the focused, systematic and routine attention to personal details for purposes of influence, management, protection or direction" (Lyon, 2007, p. 14), and as a consequence, much has been described and discussed in this literature. Most of this is not or only indirectly linked to the Internet,

such as CCTV cameras in public space, workplace surveillance practices of employers, DNA databases for policing or the tagging of consumption patterns through radio frequency identification chips or 'smart meters.' With the growing use and commercialization of the Internet from the mid-1990s onward, surveillance has also taken place through the Internet (e.g., through easy availability of background checks, and the massive collection of data to monitor and profile Internet users). Increasing transparency of individuals' actions is the result of these developments – often without their awareness. However, literature from the *surveillance studies* tradition has been criticized for being somewhat one-sided and pessimistic in its assessment of surveillance on the Internet and furthermore poor on empirical and technical detail (Bennett/Parsons, 2013).

While surveillance from the private sector is (at least in principle) subject to attempts at regulation on the national and supranational level, even if their extent is contested (see below), this is much less the case for surveillance from the public sector. As studies conducted by the OpenNet Initiative have demonstrated, Internet censorship and surveillance are becoming more technically sophisticated, and both are increasingly prevalent not only in authoritarian regimes, but also in liberal democracies (Deibert et al., 2010). As a result, the initially almost universally optimistic assessment of the emancipatory societal and political consequences of further spread of Internet use – prominently visible, e.g., in the role played by social media during the 'Arab Spring' of 2011 – has been called into question. Rather than bringing empowerment to the individual, fostering transparency and democracy, and undermining authoritarian rule, it has been pointed out, the surveillance potential of Internet technology can also be used by dictatorships to spy on dissidents, uncover their identities, and censor access to information (Morozov, 2011). The revelations of routine and widespread snooping by national security agencies that surfaced in the summer of 2013 and are discussed in a separate section below have contributed to increased sensitivity in this area in many countries.

Regulating Privacy on the Internet

Problems to protect privacy against intrusions are in principle amenable to solutions through regulation. Like in most other policy domains, attempts to impose such regulations meet resistance from interested parties and political forces opposed to regulation. But there are two domain-specific aspects that further complicate regulation of privacy on the Internet: on the one hand, due to its purposefully decentralized technical nature, there is not one single point from which the whole of the Internet can be affected by regulation; and on the other hand, attempts at regulation only started after the privatization of the Internet backbones and the opening up of the Internet for commercial use, i.e., in the mid-1990s. At that point in time, however, the Internet had already undergone a long period without any regulation, while privacy regulation had been under way for some time, both on the national and international level, without taking into account the specific problems the Internet created in that area. Attempts at regulation thus continue to take place in a highly fragmented situation, with a multitude of actors (many of whom focus not only on regulation on the Internet) and strongly diverging interests. Outcomes are therefore often characterized by conflict and blockade.

National Level Regulation

Due to the technical aspects of the Internet and the sequence of historical developments mentioned above, regulation of privacy on the national level is not primarily focused on the Internet. Privacy became a topic of political regulation in many Western democracies in the 1970s, when countries (starting with Sweden and West Germany) began to discuss and pass comprehensive privacy legislation and set up institutions charged with protecting personal information, often labeled 'privacy commissioners' or 'data protection agencies.' While reacting to common problems, national solutions varied considerably due to varying political preferences, administrative traditions, and institutional interests; but processes of diffusion and learning spread privacy legislation across the globe in the decades since (Newman, 2008). The United States, however, followed a different trajectory with a focus on performance-based regulation centering on 'fair information principles' largely developed by the administration, and supplemented by area-specific legislation instead of comprehensive legislation.

National regulators and privacy commissioners have little effective influence on the whole Internet. Their work thus mainly focuses on national level implementation of rules and questions that are amenable to national regulation. Under the heading 'Internet,' a recent report (published in 2011) of the German Data Protection Commissioner, e.g., discussed such topics as the collection of location data, WLAN access, Google Street View, and the setting up of a 'Common Internet Center' by German security authorities to fight terrorism. Such reports can influence national political debates, serve as an antagonist to security agency and law enforcement interests in the political process, and have educational effects on the general public which uses the Internet, but it is unlikely to achieve much beyond national borders. Borrowing a term from environmental policy, it can thus primarily be described as 'end-of-pipe regulation.'

International Level Regulation

Potentially more effective regulation can be achieved on the supranational and international level. Indeed, looking at privacy regulation, one can say that the international level has been leading the way here, with bodies such as the Council of Europe and the OECD being early initiators of conventions and guidelines from the 1970s onward. In 1985, the OECD first adopted a 'Declaration on Transborder Data Flows' which pledged support for international exchange of data and information and (given its focus on economic policy) framed obstacles to it as protectionist; in 1998, a 'Declaration on the Protection of Privacy on Global Networks' followed which confirmed the importance of effective privacy protection also for the future success of e-commerce. In 1995, the European Union passed its 'Directive on the Protection of Personal Data' in order to harmonize regulation across its then 15 member

states and restrict the transfer of personal data to third countries without adequate protection of personal data. Since EU directives are legally binding to member states, this had more direct impact than the previous documents which largely had the status of recommendations.

However, none of these supranational and international organizations are in a position to exercise direct regulatory power over the Internet. Indeed, who controls the Internet is both unclear and contested (Goldsmith/Wu, 2006); and given the principal decisions in favor of technological openness that lie at the heart of the Internet (see above), the fact that a single set of standards cannot be enforced universally on the whole Internet will not change. Furthermore, conceptions and priorities regarding privacy vary on the national level: European countries perceive privacy as a fundamental human right which is a precondition for an individual's autonomy; it can therefore not be given up individually, and society has a duty to protect it. In the United States, in contrast, privacy is seen as a property right that an individual can trade away if he or she chooses to, and markets are thus seen as a more effective way of protecting it than state regulation (Busch, 2011).

With divergent preferences between Europe and the US, no international regime governing privacy on the Internet could be established; instead, rival standards are the most likely outcome in such a situation, and that has indeed been the case (Drezner, 2007). As a consequence, conflicts have arisen over data protection on the Internet between the EU and the US in the past. While a compromise could be reached in the economically important area of e-commerce with the 'Safe Harbor Agreement' of 2000, outcomes have been more conflictuous and characterized by unilateral imposition of US preferences in areas related to security and antiterrorism policy, such as the questions of transferring personal data of aviation passengers (PNR) or international financial transactions data (SWIFT) (Busch, 2013).

The Internet and National Security

Information technology has been playing an ever more important role in security policy over the last decades due to the massive improvements in information and communications technology (ICT). This development was further speeded up significantly after the terrorist attacks of 11 September 2001, leading to a transformation of state activities which saw a blurring of the boundaries between foreign and domestic security policy, the blending of police, secret service, and military tasks, and a central role for ICT as a national security state tool (Busch, 2015).

The extent to which national security agencies have interfered with communication on the Internet in order to obtain information became clear after a whistleblower, the former NSA contractor Edward Snowden, published classified information from the summer of 2013 onward. It revealed comprehensive operations by intelligence agencies such as the US NSA, the UK's GCHQ, the German BND, and various others more to intercept information from the Internet and the telephone system through both indiscriminate bulk data collection as well as targeted spying under programs with names like PRISM, Quantum, Tempora, XKeyscore, or MUSCULAR. The material also made public a previously unknown level of cooperation and data sharing between these agencies which could also serve to circumvent constitutional barriers to their operations, such as a ban on spying against their own country's citizens. Apparently the NSA also had direct access to the servers of technology firms like Google, Facebook, Microsoft, and Apple (Harding, 2014).

The revelations ruffled feathers diplomatically as it became clear that the US had not only collected data from close allies such as Germany and France and bugged a fax machine of the European Commission, but had even targeted Chancellor Merkel's personal cell phone. As these transgressions were criticized in political discourse, they made clear that a number of state security agencies seemed to have overstepped their brief. A principal-agent problem had evidently emerged in the oversight of security services, and legislatures in some countries moved to tighten the reins. In the United States, for example, President Obama appointed a *Review Group on Intelligence and Communications Technologies* that reported in December 2013. Besides its 46 concrete recommendations the report emphasizes the need to "protect, at once, two different forms of security: national security and personal privacy" (President's Review Group, 2014, p. xv). It remains to be seen to what extent the Review Group's recommendations will result in changes to US policy. In any case a continuation of past practices could severely harm US business interests if customers from other countries decided not to entrust their electronic data to servers located in the US any longer.

Internet and Privacy: Outlook

Growing use of the Internet is only the latest in a string of technological developments that has imperiled personal privacy. While opinion polls show a strong preference of Internet users to protect their personal data, a number of interests combine to make use of such data, mainly for the purposes of economic growth, commercial profit, and the protection of individual and national security. While in principle regulation could help strike a balance between these competing interests, various factors have been working against this. Thus regulation of the Internet is principally difficult due to its decentralized nature on the technical level, its global connectedness and spread across many jurisdictions, and private ownership of large parts of its infrastructure. In addition, the view that states could not regulate the Internet (and that states are generally on the way out as globalization spreads) dominated for a long time, resulting in few attempts at regulation. When – parallel to the growing importance of the Internet – state attempts at regulation increased, they encountered collective action problems emanating from different preferences and regulatory path dependencies.

Whether competition between rival regulatory standards on the international level, mainly those of the US and the EU, will lead to the emergence of common solutions remains to be seen. While such regulation can affect privacy interests of Internet users, the resistance against that may in the future be less stringent than it was in the past, for attitudes in this area have changed, as a leading advocate in that field has stated: "When I first wrote the book, two ideas seemed to

dominate debate about the Net: first, that the government could never regulate the Net, and second, that this was a good thing. Today, attitudes are different. There is still the commonplace that government can't regulate, but in a world drowning in spam, computer viruses, identity theft, copyright 'piracy', and the sexual exploitation of children, the resolve against regulation has weakened. We all love the Net. But if some government could really deliver on the promise to erase all the bads of this space, most of us would gladly sign up" (Lessig, 2006, p. 27).

In principle, a third approach to the problem of protecting privacy on the Internet – besides national and international level regulation – is available, namely a technical and organizational solution applied at the level of the information system ('privacy by design,' 'privacy enhancing technologies'). While this has both been discussed and encouraged (e.g., by information commissioners) for some time, implementation has been reluctant as substantial interests exist that push, e.g., against data minimization. Whether that balance of interests will shift as the number of Internet users rises further and discussions about the "virtue of forgetting in the digital age" (Mayer-Schönberger, 2009) become more prominent, remains open to speculation. The debate following the European Court of Justice ruling of April 2014 about the "right to be forgotten" (C131/12, *Google Spain SL, Google Inc. v Agencia Española de Protección de Datos*) has demonstrated the difficulty of balancing central values such as free speech and the protection of privacy. But above all it has been known for some time that who prevails in collective action is not primarily determined by the sheer number of people involved on both sides or the quality of the argument, but rather by their relative incentives and capabilities to organize and gain influence on the political decision-making process (Olson, 1965).

Botnet	A group of computers that are connected to the Internet and under the control of a malicious party, typically after malware (such as a virus program) has been executed under legitimate use.
Data mining	A process of attempting to discover meaningful patterns in (often very large) sets of already collected data without prior forming of hypotheses.
Privacy enhancing technologies (PET)	Technological, procedural, or organizational tools to enhance user control over their personal data.
Radio frequency identification (RFID)	A wireless technology that uses electromagnetic fields to transfer data, mostly without battery, from a tag attached to an object to identify its properties.
Total information awareness (TIA)	Program run by the US Department of Defense after 11 September 2001 to integrate information from diverse sources. After allegations of privacy violations funding was withdrawn in 2004.
Ubiquitous computing	A paradigm of computer use in which many, often mobile and networked computers replace the one traditional desktop computer

Internet and Social Media: Anthropological Aspects

Paula Uimonen, Stockholm University, Stockholm, Sweden

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Generally defined as a network of networks, the Internet has had a profound impact on the social organization and cultural meaning of modern society. Since it entered the public domain in the early 1990s, the Internet has grown exponentially and is now used by one-third of the world population. Anthropologists have studied the Internet from its early social history, especially in non-Western countries. Over time, this research has evolved into the subdiscipline of digital anthropology, which studies the development and use of digital media in different cultural contexts.

Cyberculture and Digital Anthropology

Generally defined as a network of networks, the Internet has had a profound impact on the social organization and cultural meaning of modern society. It is a media technology that has grown at an exponential rate: from being used by approximately 2% of the world population in 1997 to 35% or 2.45 billion people in 2011 (estimates by International Telecommunication Union). The growth in social media use, also known as Web 2.0 technologies, has been equally staggering. Since it was launched to the public in 2006, Facebook grew from 100 million users in 2008 to 1 billion in 2012. Meanwhile, Wikipedia, Twitter, and YouTube have become commonplace sources of information, communication, and entertainment, while new touchscreen interfaces have facilitated the interactive use of digital media, across generations.

The Internet was originally developed by and for researchers, to enable them to share costly computer resources. The first manifestation of the Internet was the Advanced Research Projects Agency Network (ARPANET) in the United States. From the outset, the Internet built on the idea of 'open-architecture networking' or what came to be known as Transfer Control Protocol/Internet Protocol, allowing interconnections or 'internetting' between different computers and computer networks (see *Brief History of the Internet* published online by the Internet Society). From the late 1960s and onward, the Internet grew steadily in research communities around the world, first in the United States, but as of late 1980s in other parts of the world as well. It was the usefulness of being able to share computer resources combined with the popularity of e-mail, which was introduced in 1971 that spread the Internet around the world. The Internet was originally funded by the US Department of Defense, but its purpose was to strengthen research. It was only in the early to mid-1990s that the Internet became public and commercial. As the Internet entered the public domain, it was suggested that it was originally built by the military to withstand nuclear war. While this interpretation of the origins of the Internet have been vehemently denied by the scientists who were involved in its design, it offers an interesting 'origin myth' of what was initially known to the public as an unregulated, even anarchistic, global media technology, the development of which was inspired by the countercultures of the 1960s (Castells, 1996; Uimonen, 2001).

Already in 1994, Arturo Escobar encouraged anthropologists to engage in a field of inquiry that he referred to as the 'anthropology of cyberculture. Underlining that all technologies are cultural interventions and that science and technology constitute 'crucial arenas for the creation of culture in today's world, Escobar (1994: p. 211) encouraged anthropologists to 'venture into this world in order to renew their interest in the understanding and politics of cultural change and cultural diversity. His reading of cyberculture did not necessarily refer to the Internet, which was mentioned in a footnote, but focused on computer, information, and biological technologies, primarily from the perspective of science and technology studies (STS). Even so, his interest in cyberculture was clearly inspired by emerging work on cyberspace, a term he used more widely than Internet in the paper. At the time, some anthropologists were also inspired by the concept cyborgs, which was introduced by feminist scholar Donna Haraway (1991) to describe fabricated hybrids of machine and organism. Sociologist Sherry Turkle (1995) was another influential scholar, and her work on human–computer interaction inspired many anthropologists for years to come (Garsten and Wulff, 2003). In the 1990s, some anthropologists referred to their Internet research in terms of cyberanthropology, but the term fell out of use. Alternative ways of classifying Internet research included digital ethnography, Internet ethnography, virtual ethnography, virtual anthropology, and eventually digital anthropology, which has evolved into the most common way of describing this research field.

In August 2010, the European Association of Social Anthropologists (EASA) organized a workshop in Digital Anthropology at the biennial EASA conference in Maynooth, Ireland, a milestone in the evolution of this subdiscipline. The first of its kind at EASA, the workshop was convened by Daniel Miller and Heather Horst, two of the leading researchers in this field, with presentations by senior and junior Internet anthropologists. In 2012, a Center for Digital Anthropology was established at the University College of London (UCL), directed by Daniel Miller. Over the years, digital anthropology has also been taught at different universities in Europe and United States. In August 2008, the Department of Social Anthropology at Stockholm University initiated a graduate course in digital anthropology led by Paula Uimonen, in 2009 the UCL launched an MSc program in digital anthropology

directed by Daniel Miller, and in 2012 the first textbook in digital anthropology was published (Horst and Miller, 2012). In the United States, Michael Wesch at Kansas State University has been leading a Digital Ethnography program, Christopher Kelty has been teaching courses about the Internet at University of California, Los Angeles, and Tom Boellstorff has been teaching courses in virtual anthropology at University of California, Irvine, to name some contemporary digital anthropologists.

Digital anthropology is closely related to media and transnational anthropology, as well as STS and visual anthropology. Topics related to digital anthropology are often discussed in the *Media-Anthro* mailing list of EASA's media anthropology network as well as *Savage Minds*, the most popular blog for anthropologists. There is also a digital anthropology group in the *Open Anthropology Cooperative* (OAC), a social networking site where many disciplinary specializations in anthropology coalesce. The OAC was initiated in 2009 by Keith Hart, one of the first anthropologists to write about Internet, social transformation, and world society (2000).

Research topics in digital anthropology combine distinguishing features of digital media with typical areas of interest for anthropologists, such as cultural identity, power structures, and social networks. Many researchers in digital anthropology are experienced in other research areas, bringing broader insights into their digital work. For example, Daniel Miller is well known for his work on material culture and consumption, while Tom Boellstorff has done a lot of work on globalization and sexuality. As younger scholars now turn to digital anthropology there will probably be a greater specialization in this research field, but hopefully future generations of scholars will also broaden their research interest to other anthropological domains. After all, digital anthropology is no different from other subdisciplines within anthropology in that it builds upon as well as contributes to developments in mainstream anthropology. Meanwhile, a growing number of anthropologists are paying attention to digital media in their studies in other domains, not least in the fields of transnational migration, diaspora, material culture, popular culture, and social movements. This body of research is also contributing to anthropological analyses of digital media. For an overview, see Coleman (2010).

According to a recent definition, 'digital anthropology focuses on the development and use of digital media and communication technologies in different social and cultural contexts' (Uimonen, 2012: p. 36). It is still an emerging subdiscipline, which does not have a theoretical canon, but draws upon the accumulated body of anthropological knowledge in general, and related research fields or subdisciplines within anthropology in particular. Digital anthropologists carry out fieldwork online as well as offline, often combining traditional ethnographic research methods with more experimental methods such as multisited and online ethnography (Kelty, 2008), ethnographic fieldwork in virtual worlds (Boellstorff et al., 2012) or participatory digital video (Uimonen, 2012). Like many other research fields in anthropology, digital anthropology originates from scholars based in Europe and the United States, but their fieldwork is often carried out in non-Western contexts, thus focusing on cultures that tend to be underinvestigated by digital media scholars from other disciplines. With time, the research domain will hopefully be more globalized, attracting anthropologists from all parts of the world, especially Africa, Asia, and Latin America.

Hyperbole and Social Change

Ever since it entered the public domain, the Internet has been cast in hyperbolic predictions of radical social change. Embedded in discourses on the information society or knowledge society, the Internet has been thought to usher in a new era in human development, the information age. Utopian champions have envisioned new premises for democracy and openness, while dystopian critics have warned of increased surveillance and government control. Similarly, optimistic predictions of enhanced individual freedoms have been countered with gloomy reports of the online circulation of legally prohibited and morally offensive content. Some of the most influential predictions have related to changes in the economic system, the virtual economy offering new premises for growth and value creation in global capitalism. These utopian forecasts have even influenced stock markets as exemplified in the 'dot com' boom, when newly established Internet companies of various kinds were estimated to be worth considerable amounts of money in their initial public offerings. The ensuing dot com crash revealed the false premises of many of these speculative estimates, although some of the dot coms managed to survive in the long term. It was perhaps no coincidence that the dot com bubble took place around 1997–2000, concomitantly with the millennium shift, utopian expectations of a new virtual economy thus coinciding with an epochal shift in human history. At the time, dystopian predictions of disaster were also quite influential, as exemplified by the Y2K (year 2000) debate. As the calendar shifted to year 2000, technical date standards were considered to be problematic and unless remedied, societies could face technical failures of unknown proportions. The Y2K problem caught the attention of governments and even the United Nations, and substantial resources were invested into fixing the 'millennium bug. To date, it remains unclear whether the Y2K problem was exaggerated or real, but billions of US dollars were spent fixing it.

Historical changes coinciding with the millennium shift have also been anticipated by social scientists, the most influential one being the sociologist Manuel Castells and his theories of the 'network society. In the years leading up to the millennium shift, Castells published his trilogy *The Information Age: Economy, Society and Culture*, comprising the volumes *The Rise of the Network Society* (1996), *The Power of Identity* (1997), and *End of Millennium* (1998). Leading sociologist Anthony Giddens referred to Castells as the 'new Weber, thus equaling his analysis of the information age with Max Weber's theories of the industrial age. A basic tenet in Castells' work is the notion that networks have become the dominant social structure in the age of informational capitalism, characterized by 'space of flows, 'timeless time, and 'culture of real virtuality. His understanding of the network society is heavily influenced by the Internet, the

technological configuration of which he draws upon when describing this new social structure, but he extrapolates social changes to all domains, cultural, economic, and political. Castells has been criticized for technological determinism, but remains one of the world's most well-cited scholars on matters related to Internet, power, communication, and globalization.

From an anthropological perspective, notions of technology-induced social change can be interpreted as forming part of the narratives of modernity framing Internet development. By approaching technology from the perspective of 'social constructivism, the STS school has been able to problematize this common understanding of progress, while deepening our understanding of the role of technological determinism in notions of modernity (Escobar, 1994). Bruno Latour, sociologist of science and self-proclaimed anthropologist of modernity, is an influential scholar in STS, and one of the key theoreticians of Actor–Network Theory. Latour (2005) challenges the modernist distinction between nature and culture, while focusing on social transformation through mediators, which can be human or nonhuman agents, and their acts of translation or mediation in networks of relations.

More recently, social media have been the subject of popular and scholarly claims of radical social change, as exemplified by discourses on the Twitter and Facebook revolutions in North Africa and the Middle East in 2011. Although social scientists as well as social activists have vehemently challenged the suggestion that social media played a critical role in the popular uprisings of the 'Arab spring, mainstream Western media have perpetuated this view, not least by retransmitting information from various online sources. Media professionals have joined politicians, business representatives, and civil society advocates in praising the revolutionary power of social media, while techsavvy hackers have helped local activists bypass Internet censorship introduced by nervous governments.

This second wave of hyperbole has been more focused on media than technology, reflecting the ubiquity and convergence of technological interfaces that has taken place over the last decade. Some scholars still distinguish between 'new' media and 'old' media, thus accentuating differences between digital media and other media. The emphasis on 'social' media is a good example of this logic. All media are in fact social; they are 'machineries of meaning' or 'cultural technologies' (Hannerz, 1996). Each medium has its own characteristics, whether print or broadcast, but they all convey shared meanings between people. Social media are supposed to be different from other media in that the producer is also the consumer, there is a greater degree of interaction, and user-generated content can be created, exchanged, and circulated with considerable ease. With the advent of 'smart phones, social media have become even more accessible, and in addition to mobile interfaces of popular sites, new interactive mobile applications are constantly developed. Although these decentralized and interactive features have characterized the Internet all along, new technological interfaces have made them more accessible, thus contributing to their popularity as well as the hyperbole framing their use.

Anthropologists tend to offer a more empirically grounded appraisal of digital media and social change. Rather than taking radical claims at face value, anthropologists use their knowledge and methods to determine what changes are *de facto* taking place in a given cultural context, and how these changes are influenced by and in turn influence the development and use of digital media. In so doing, anthropologists can build upon one of the main theorems of digital anthropology, namely the intricate interlinkages between online and offline social worlds. From the outset, anthropologists have insisted that the Internet should not be viewed as something that stands apart from society, affecting it from the outside, but rather something that is socially embedded, the Internet both influencing and being influenced by society (Miller and Slater, 2000; Uimonen, 2001). More recently, this argument has been made in relation to virtual worlds, Boellstorff (2008) underlining that the virtual is not opposed to the real but to the actual. The argument has also been made and creatively illustrated in relation to social media. Michael Wesch's early analysis of social media and hypertext underlines the human essence of the Internet. His introductory YouTube video *Web 2.0… The Machine is Using Us* has proven quite popular and has been viewed by over 11 million people since it was posted in January 2007. In his recent Facebook ethnography, Miller describes the profound impact of this online platform for the management of social relationships, while explaining that individuals have always been social networking sites (Miller, 2011).

This insistence on the interconnectedness of the virtual and the real, online and offline social worlds, digitally mediated and nonmediated interactions enable anthropologists to grasp momentary as well as lasting changes brought about by digital media, transformations that build upon as well as alter existing social realities.

A complementary way of determining social changes introduced by digital media is through Internet ethnography that is, ethnographic studies of technological development. Since the Internet, like all technologies, is a social construct, it is possible to ethnographically study the people who are developing the technology, along with the cultural values and meanings that influence their work. In other words, the very stuff of social embeddedness – the people who develop the technology – can also be ethnographically investigated. In his detailed study of computer geeks in different places in Asia, Europe, and the United States, Christopher Kelty (2008) is able to identify the cultural significance of free and open source software. The cultural meanings and social practices of software developers offer an ethnographic entry point into a much broader appraisal of how technological standards interact with and influence societal trends. Thus Kelty is able to show how the cultural practices of 'recursive publics' are impacting other social domains, well beyond software development. In an earlier Internet ethnography, Uimonen (2001) could show how the activities of Internet pioneers were influenced by and in turn helped influence the cultural meaning of the Internet in various developing countries, thus spreading not only Internet technology but also the 'culture of networking' to different parts of the world.

Internet and Globalization

Inseparable from the broader process of globalization, the Internet has contributed to the interconnectedness of the world, as evidenced in the intensification of transnational flows of people, ideas, goods, and services over the last few decades. The Internet has also connected people around the world in a myriad of decentralized networks of multimodal communication and interaction. Now that the public Internet has been around for two decades, especially in the well-connected rich economies of the world, it would be difficult to imagine a world without global interactivity. But it was not long ago that a fax machine was the cheapest and fastest way to communicate with people in distant places, the facsimile being a precursor to e-mail, in terms of speed and reach even more so than ordinary mail – or what came to be known as snail mail when e-mail took over written communication. Similarly, it was quite recently that satellite TV opened up the world to us, and before that television. Within years of becoming public, the Internet has brought us interactive media, making users consumers, producers and distributors of multimedia content. The change has indeed been remarkable, but perhaps not quite as radical as is often assumed, since the uneven spread of digital media has also highlighted the continuation of historically shaped inequalities around the world, especially the perpetuation of center–periphery relations.

Anthropological analyses of globalization help identify the cultural significance of the global spread of the Internet. While media scholar Marshall McLuhan used 'global village' primarily in relation to television in the early 1960s, the term was reinvigorated through the rapid growth of Internet use. Unfortunately, the concept global village portrays a somewhat illusory notion of social harmony and is therefore of limited explanatory value (Hannerz, 1996). By contrast, anthropologists have theorized the social and cultural significance of global interconnectedness, including more conflictual aspects like asymmetric center–periphery relations. Anthropological theory building on globalization pays close attention to the role of media in transnational flows and imaginaries, as exemplified in the work of Ulf Hannerz (1996) and Arjun Appadurai (1996). Indeed, some of the most advanced anthropological theories of globalization have preceded the Internet, yet help explain it. In a paper published in 1992, Ulf Hannerz referred to world society, or the 'global ecumene' as he called it, in terms of a 'network of networks. This was before the Internet, which is generally defined as the network of networks, had entered the public domain. Hannerz' elaborations on social networks built on his earlier work in urban anthropology (1980), where he had already described the city in terms of a network of networks. In his later work, he introduced the concept 'network of perspectives' to capture the social organization of cultural meaning in an increasingly interconnected world. Since they precede Castells' elaborations on the network society, anthropological network theories offer a complementary perspective on the global network society.

The global spread of the Internet has been accompanied by discourses on the 'digital divide, a concept that refers to uneven patterns of access and use, especially the gaps between the global North and the global South. Digital divides are also found within societies, such as gaps between rural–urban, old–young, educated–illiterate users and non-users. These gaps reflect the uneven distribution of infrastructure, not least electricity, as well as skills and abilities. Digital discrepancies are also evident in the production of digital technology, the availability of digital content, and the disposal of digital artifacts. Labor-intensive hardware is produced in low-cost countries, very little online content is produced by and for peripheral cultures, and computers discarded in Western countries are shipped to developing countries for redistribution. The availability of digital technology tends to follow patterns of overall development, the richest countries in the world being the most well-connected. Inspired by the binary logic of digital technology, Castells discusses the digital divide in the global network society in terms of inclusion and exclusion, while referring to the least connected and thus the most excluded continent in the world, Africa, in terms of the 'black hole of informational capitalism' (Castells, 1998: pp. 161–165). This binary view is, however, somewhat limited.

Anthropological analyses offer a more nuanced understanding of digital stratification, as exemplified by the concept 'partial inclusion' (Uimonen, 2012). Instead of looking at social inequalities in binary terms, an emphasis on patterns of digital stratification allows for a more varied appraisal of access and use in different parts of the world. From this perspective, it becomes clear that access and use in the peripheries can be a matter of partial inclusion in the global network society. In many parts of the world, access is shared and available in designated areas only (computer labs, Internet cafes, offices), while digital media skills can be quite rudimentary. Even so, these islands of connectivity can stimulate perceptions of global interconnectedness, thus corresponding to local aspirations for membership in modern world society (Ferguson, 2006). Limited as it may be, the state of partial inclusion is indicative of much broader social and cultural patterns that are of great interest to anthropologists in their quest to understand and explain the current state of the world.

The ways in which digital media are used in different parts of the world, not least in the peripheries, can also shed light on the social and cultural significance of transnationalism and translocality. From early on, anthropological studies have shown that far from erasing local identities, the Internet tends to reinforce a localized sense of belonging. If anything, the Internet helps people explore their cultural identities, a process that has been described in terms of 'expansive realization' and 'expansive potential' (Miller and Slater, 2000). At the same time, the Internet can also stimulate a more cosmopolitan identification with the world at large (Miller and Slater, 2000; Hart, 2000; Uimonen, 2001, 2012). If anything, the Internet clarifies the extent to which people have become connected to many more places than the place where they may physically live or reside. Through the Internet, people can manage their translocal and transnational social relations, thus maintaining both local and global cultural identities. The Internet is also stimulating the expression of more hybrid and creolized identities, especially through visual interfaces like Facebook (Uimonen, 2012).

Online Knowledge Production

The Internet opens up new possibilities for anthropological knowledge production, while raising new challenges. The Internet enables online fieldwork, which does not require the physical relocation of the researcher. Compared to travel to distant localities for an extended period of time, this is a less costly and in many ways more convenient way of carrying out fieldwork. It is still rare, however, that anthropologists carry out their research solely online. Boellstorff (2008, 2012) is a notable exception with his ground breaking fieldwork in the virtual world Second Life. It is more common that anthropologists combine on- and offline fieldwork, often feeling more comfortable having face-to-face encounters with informants in their offline environments as well as online. Online fieldwork also has the benefit that large amounts of field data can easily be gathered and stored. For instance, social media like blogs and Facebook retain all user data for many years. In the case of blogs, the material is even publicly available, while Facebook requires a relation with the page owner. This can of course easily lead to data overload since the amounts of information can be overwhelming. Neither is it always certain that websites remain online, making online content rather precarious. Another challenge is that the Internet develops at a rapid pace, making it rather stressful to keep abreast of technological developments. Many anthropologists are challenged by technology and shun away from the Internet, keeping their own use at a minimum. In general, digital anthropologists are drawn from anthropologists with a keen interest in digital media, i.e., more geeky anthropologists, although this is by far not a prerequisite. Younger generations of anthropologists tend to be more techsavvy and thus less hesitant or shy about doing research through and about digital media.

Online research raises new ethical issues, from informed consent to the protection of identities. Similarly to offline public places, it is quite impossible to get informed consent from users of an online forum, especially over a longer period of time. It can also be difficult to disguise the real identities of informants when research results are published in audiovisual formats online. And while anthropologists may be used to doing research about peoples who will not read their work, online research is often understood and in many cases challenged by informants. There are no clear cut answers to these issues, but anthropologists need to face them as they venture into brave new online worlds.

When it comes to data gathering, anthropologists can look forward to exciting opportunities. Over the last decade, digital technology has become more accessible and affordable. Digital recording devices like cameras, video cameras, and sound recorders are now readily available, at reasonable costs. Technological convergence makes these tools even more easy to use. With a smart phone, the researcher can record images, film, and sound, and upload these online, while a new generation of digital cameras enable the user to upload images to the Internet straight from the camera. As the devices become more easy to use, new opportunities are also opening up for participatory interactive research, since informants can be equipped with digital cameras or videos and create their own digital stories. Technological advancements are paving the way for more visual and sensory ethnography, as the researcher is better able to record field data gathered through all senses. In this regard, digital anthropology can benefit from the work carried out in the fields of visual anthropology and the anthropology of the senses.

Online publication of anthropological knowledge is still in its infancy, but interesting explorations have already begun. Although some of the earliest monographs were accompanied by websites (Miller and Slater, 2000; Uimonen, 2001), these sites were mainly textual and after a few years they ceased to exist. Kelty's *Two Bits* (2008) was a ground breaking example of online publication. True to his subject matter of free and open source software, Kelty's entire monograph is available online, for download and/or modulation. The blog where the book is posted, http://twobits.net/, lists comments, and points users to other sites where the book is reviewed and debated.

More recently, Uimonen's (2012) monograph on digital media in Tanzania has been published with an accompanying website with photos and videos from fieldwork as well as a hyperlinked ebook. Published in Routledge's new book series *Innovative Ethnographies*, the monograph *Digital Drama* explores innovative forms of ethnographic representation. The book and the series website weave together visual and audiovisual narratives in artistic formats, *Digital Drama* is the first ethnography of digital media in an African context and the ebook version is hyperlinked with the book's website, at http://www.innovativeethnographies.net/digitaldrama.

Anthropological perspectives on Internet and social media can clearly advance our understanding of the social and cultural impact of digital media in our interconnected world. As Escobar noted in the early days of digital anthropology, 'cyberculture, moreover, offers a chance for anthropology to renew itself without again reaching, as in the anthropology of this century, premature closure around the figures of the other and the same. These questions, and cyberculture generally, concern what anthropology is about: the story of life as it has been lived and is being lived at this very moment' (Escobar, 1994: p. 223).

Internet Research: Ethical Concerns

Annette N Markham, Aarhus University, Aarhus N, Denmark
Elizabeth A Buchanan, Center for Applied Ethics, University of Wisconsin-Stout, Menomonie, WI, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Across the globe, societies are experiencing significant flux and transformation in the way digital information and networked technologies are woven into and influence everyday life, workplace practices, social norms, and institutional structures. Likewise, all academic disciplines are challenged to make sense of these transformations in light of ethical research practice. Actively confronting these challenges means not only being aware of them, but thoughtfully considering how we might better address these challenges. This article discusses various ethical challenges in applied research involving digital media or Internet-related contexts.

Introduction

Ethical considerations are a constant companion for any researcher. Whether one is in the hard sciences, social sciences, humanities, or some inter- or intradisciplinary space, researchers face a continuum of choices and decision points around benefits, harms, and risks in their work. Ethical research explores what is possible, just, and fair in a given context. Internet research, broadly conceived, provides numerous avenues for researchers across the disciplines: New methods, newly constituted forms of data, novel forms of data collection, and once unimaginable mixing and reuse of data have emerged in the rich and fertile Internet landscape of social media applications, big data streams, and the conglomeration of technologies into discrete data streams. This article will discuss various ethical challenges in applied research involving digital media or Internet-related contexts.

Ethical issues are more obvious in certain situations than others, such as drug testing on human subjects. Here, potential harm is anticipated and analyzed in advance; the participant in the study is physically present; and the vulnerability of the participant is more readily recognized. In other research situations, the dilemmas might not be so clear. Blood samples from a previous study might become a convenient sample for a researcher looking at a certain population's propensity for schizophrenia. Any harm to individuals who gave the blood anonymously for a diabetes study – four decades ago – might seem minimal. Still, if a study of this blood shows that a particular indigenous tribe located in Arizona was not really indigenous, plus they have a tendency toward schizophrenia, this knowledge can cause significant psychological harm to the tribal community. This actually happened, and the spark occurred when a tribal member attending a medical conference in Washington, DC suddenly discovered this information about her tribe, the Havasupai, while listening to a professional colleague's report of these findings. (This case involved blood and DNA samples taken from the Havasupai Indian tribe in Arizona. See http://www.whoownsyourbody.org/havasupai.html.) This case is a prime example of individual and group harms that can occur as a result of research activities, even those that rely on 'anonymous' data or specimens.

In research situations involving the Internet and digital materials, ethical questions have focused for many years on such areas as representation, privacy, the nature of public data, and identities. These questions include: What counts as a human? Can a person's avatar in *Second Life* or another virtual world qualify for privacy protection? What about one's LinkedIn or Facebook profiles, should these be considered authored texts or representatives (avatars) of individuals? Do platform developers, marketers, journalists, or researchers have the right to examine our online activities, simply because they are publicly available? Do companies have the right to conduct mass experiments on users of their technological platforms? Given current capacities to track, collect, archive, and analyze our digital traces, is it even possible to entirely protect or anonymize our personal data? What happens when our participants want to be given credit for their participation? How do we balance a requirement to protect privacy through anonymity with a competing request to ensure publicity through nonanonymity?

These questions have no definitive answers from a technological, social, or legal point of view, but different disciplinary approaches have been offered, as have recommendations from various federal research agencies, such as Canada's Tri-Council, Norway's National Committee for Research Ethics in the Social Sciences and Humanities, and the U.S. Secretary's Advisory Committee to the Office for Human Research Protections.

Ethical practice is essential to responsible research, yet the parameters to guide such practice are neither universally accepted nor straightforward. This article will summarize persistent contemporary dilemmas of Internet-related research and outline some of the ways these dilemmas have been or might be better addressed by legislators, research communities, and scientific research oversight committees. Because the topic of Internet research ethics has undergone significant changes in recent decades, this article strives to present the most current articulations within these changing conversations. Hence, it presents strong ethical decision making as a case-based, inductive process, rather than a practice of narrow or strict interpretations of legal or institutional guidelines. The reader is urged to consider this stance within the legal, institutional, regional, and cultural parameters of the specific research project or situation. (This may become an issue of critical concern when doing research that involves information or persons outside one's own legal and cultural boundaries. Beyond knowledge of basic philosophical principles and extant

guidelines, researchers must be aware of legal requirements in the countries involved. This can create important and potentially unresolvable tensions that should be acknowledged (Markham and Buchanan, 2012).) To note, this discussion is not intended as a set of codes or guidelines, but as an overview of how ethical discussions have shifted in the United States because of the complications brought about by technologies and capacities associated with digital materials and the Internet.

The material in this article is largely based on ethical discussions within the general research arena of Internet Studies. More specifically, it reflects the stance developed by the Association of Internet Researchers (AOIR). Some of the material in this article is derived directly from the 2012 report coauthored by Annette Markham and Elizabeth Buchanan with feedback from the AOIR Ethics Working Committee (Markham and Buchanan, 2012). Readers should check the AOIR Web site for the most recent updates about these issues.

Origin of Ethical Guidelines for Scientific Research

Grave ethical missteps in research environments involving people prompted a worldwide response in the mid-late twentieth century. Most ethics guidelines were created with the specific goal to protect persons. Several documents now serve as a foundation for the ethical treatment of persons in research studies or as they are often known, 'human subjects,' including the UN Declaration of Human Rights (1948), the Nuremberg Code (1949), the Declaration of Helsinki (1964), and the Belmont Report (1979). As Markham and Buchanan (2012) note, "the basic tenets shared by these policies include the fundamental rights of human dignity, autonomy, protection, safety, maximization of benefits and minimization of harm, or, in the most recent accepted phrasing, respect for persons, justice, and beneficence" (p. 4).

Not exclusively, but especially in the United States, these three principles – respect for persons, justice, and beneficence – have been operationalized in specific ways. This is very briefly reviewed below.

Respect for Persons

In principle, this means that individuals should be treated as autonomous beings, capable of making their own decisions. In addition, it is recognized that certain persons should receive additional protections if they have less autonomy. This category of vulnerability includes, for example, young, disabled, pregnant, or incarcerated persons. In practice, or as described within many regulatory documents, this principle has been translated to informed consent. Persons must be given adequate information, clearly understand the risks and benefits of a study, and be able to make a voluntary decision to participate. They must also be allowed to choose to end their participation at any time.

Justice

The initial concept of justice as envisioned by the Belmont Report focuses attention on fairness of distribution of scarce benefits. This essentially means that equal people should be treated equally, or that people should not be denied the benefits of research without good reason. In practice, this concept has been operationalized to mean that the selection of research subjects should be fair so that not only certain select groups gain from the benefits or suffer the risks of such research. This concept has been extended to include fair access, so that persons have an equal opportunity to participate in studies that might benefit them, as in the case of innovative methods, procedures, or therapies in biomedical clinical trials.

Beneficence

This principle holds that humans should not be harmed in the course of study. In practice, at least in the United States, harm is assessed in relation to a risk–benefit analysis. If the benefit is seen to be great, this may outweigh the risks or costs. This utilitarian approach differs significantly from other cultural contexts that promote a more deontological approach. For example:

> [At] least on an ideal level, European approaches tend to emphasize more deontological approaches – i.e., approaches that take basic human rights (self-determination, privacy, informed consent, etc.) as so foundational that virtually no set of possible benefits that might be gained from violating these ethically justifies that violation.
>
> Ess and The AOIR Working Committee, 2002

Ethics of Research in the Digital and Internet Age

In line with the basic principles outlined in the Belmont Report and other international documents, the AOIR finds the following principles to be fundamental to an ethical approach to Internet research:

The greater the vulnerability of the community/author/participant, the greater the obligation of the researcher to protect the community/author/participant.

Because 'harm' is defined contextually, ethical principles are more likely to be understood inductively rather than applied universally. That is, rather than one-size-fits-all pronouncements, ethical decision making is best approached through the application of practical judgment attentive to the specific context.

Because all digital information at some point involves individual persons, consideration of principles related to research on humans (versus data) might be necessary even if it is not immediately apparent how and where persons are involved in the research data.

When making ethical decisions, researchers must balance the rights of subjects (as authors, as research participants, as people) with the social benefits of research and researchers' rights to conduct research. In different contexts the rights of subjects may outweigh the benefits of research.

Ethical issues may arise and need to be addressed during all steps of the research process, from planning to publication and dissemination.

> Ethical decision-making is a deliberative process, and researchers should consult as many people and resources as possible in this process, including fellow researchers, people participating in or familiar with contexts/sites being studied, research review boards, ethics guidelines, published scholarship (within one's discipline but also in other disciplines), and, where applicable, legal precedent (Markham and Buchanan, 2012, footnotes removed).

Even with these starting points, ethical conundrums arise and are rarely easy to resolve when encountered during a research project, due to multiple competing or conflicting values and norms at play in any situation. Likewise, different ethical issues arise at different critical junctures of a project, when the researcher is making logistical or methodological decisions about how to collect, manage, analyze, and interpret what might be called data, or how to present the results of one's research.

Persistent Dilemmas in Conceptualizing Ethical Considerations

We have found that Internet or digitally related contexts present sticky or persistent ethical dilemmas for social researchers. These could be discussed in many productive ways, through the lenses of philosophy, research methods, design, everyday use, work practices, and so forth. Here, four complications most directly related to the core tenets of ethical research guidelines are discussed: human subjects, privacy, personally identifiable information, and informed consent. These four concepts bring with them irresolvable tensions, as Markham and Buchanan (2012) note, since there are many ideas, values, and stakeholder interests competing in how these concepts get defined or actualized, whether in a general sense or in the specific context of a study. Rather than delimiting debate around these issues, we take the stance that they are best understood and managed in the most ethically sensible way, according to the needs determined by the specific research case. (For more philosophical discussion of phronesis as applied to digital research ethics and decision making, see the first version of the AOIR ethics report (Ess and the AOIR Ethics Working Committee, 2002) or Ess, 2009.) While general research ethics principles guide the work of ethics review boards as well as researchers, each and every case and context is unique and presents nuances for consideration.

Human Subjects

As written in the AOIR ethics guidelines (2012): "The concept of 'human subjects' is a persistent and contentious example of a dialectical tension between disciplinary/regulatory models and context-specific sensibilities" (p. 6). Emerging directly from biomedical research practices, the term 'human subject' is used broadly across all research disciplines in the United States as a baseline determinant of whether or not the research project should undergo ethical supervision. Yet this term "has been long critiqued for being ill-suited for models of inquiry that follow non-biomedical procedures for interacting with people" (p. 6), such as ethnographic observation or interviews. This ill fit becomes more apparent when deciding whether or not digital information qualifies for human subject protections and if so, how. As Markham and Buchanan clarify, the answer is not easily determined by relying on traditional or regulatory frameworks:

> Manipulation and close study of information generated by social media networks certainly constitutes a different research environment than sticking a needle into a volunteering person in a medical laboratory. On the other hand, entire communities have felt harm from use of their DNA data more than a decade after it was collected and anonymously aggregated. Interacting with a person in a face-to-face interview seems to raise different considerations than interviewing a person in an anonymous chatroom. Yet, anonymous members of online communities have felt harm after researchers published reports about what they perceived to be private community activities. Blogs are often considered public, published texts. On the other hand, users have described their blogs as a part of their identity, not to be treated as simply publicly accessible data.
>
> 2012: p. 6, including footnote text

Thus, the term 'human subject' may not be suitable as the baseline prompt for considering potential ethical questions. As AOIR concluded in the 2012 guidelines:

> [W]hen considered outside a regulatory framework, the concept of 'human subject' may not be as relevant as other terms such as harm, vulnerability, personally identifiable information, and so forth. We encourage researchers to continue vigorous and critical discussion of the concept of 'human subject,' both as it might be further specified in internet-related research or as it might be supplanted by terms that more appropriately define the boundaries for what constitutes inquiry that might be ethically challenging.
>
> Markham and Buchanan, 2012: p. 6

Privacy Concepts

Not only is our personal privacy a crumbling myth, the concept itself is contested and ambiguous. Researchers struggling with the practical and methodological challenges surrounding the issue of privacy find themselves on constantly shifting conceptual terrain. The term 'privacy' is almost always discussed as a binary that contrasts private with public. The effort on one level is to determine what constitutes public versus private, which has been seen as a useful way to guide one's actions in relation to this determination. Researchers typically use this distinction to help decide whether the material is a published text or a person, or to determine whether and how privacy needs to be protected.

Distinguishing privacy in relation to notions of the public is problematic on many levels. Commonly, people use publicly accessible information spaces but maintain strong expectations of privacy. Ikonomidis Svedmark and Nyberg (2009) interviewed dozens of Swedish youth (ages 15–25) who posted revealing pictures of themselves in public online spaces, such as blogs. Their responses revealed a complex and ambiguous understanding of privacy. As one Swedish girl put it: "I have this blog online because it's the only place where I feel safe and be sure my parents won't find it. If it had it in a diary in my room, they would find it."

This sort of experience of perceived, rather than actual, privacy has guided much of our current thinking about privacy and ethical social Internet research. Sveningsson (2003) argues that privacy is not only a continuum, it is

also a concept understood in relation to whether the information/content/context is considered sensitive or nonsensitive. She offers the following grid, which has been useful in broadening the conceptualization of privacy in digital contexts (Figure 1):

While this model is a useful progression from earlier notions of public and private, it remains problematic because the definitions remain embedded in binaries that do not adequately encompass experience or attitudes about privacy, sensitivity, and vulnerability. What is 'private' remains predominantly a location or state, opposed to or separate from 'public.' Questions about privacy in research design and process, then, also center on this binary, and the main question remains: "What is public/private?" This is the wrong question in contexts where one's information flow is constant and public, where people are always-connected, or where cutting, pasting, forwarding, reposting, and other mashup practices remix our personal information in globally distributed, complex networks.

Figure 1 Sveningsson's model of Internet privacy, 2004.

McKee and Porter (2009) add other dimensions to Sveningsson's model to make more fine-grained distinctions (Figure 2).

This model adds more dimensions to how we might assess a research context, along various continua. They argue that in making decisions about whether or not a researcher needs to gain consent, the researcher should consider the extent to which the context might be public or private, how likely it is that the material or data might be connected to an individual or not, how much interaction the researcher has with a person, the level of sensitivity of the topic, and the vulnerability of the person involved. As with Sveningsson's model, this graphic retains a binary distinction between public and private. It presents a useful tool to think with, but can create other sets of binaries that become problematic in practice. When we try to use this model to explain tough cases, its utility breaks down.

It is quite common that people acknowledge that the substance of their communication is public, but are shocked when the information is taken out of context or used in a way that is unexpected or unwanted. For example, youth interviewed by Danah Boyd and Alice Marwick (2011) felt angry that their Facebook information was used by teachers and administrators in a school-wide public presentation to illustrate the dangers of posting private information in public spaces. They knew the information was relatively public. It was the manner in which it was used that made them feel violated (p. 6). Context, more than type of information, was the critical consideration. A similar attitude is expressed by the Swedish youth mentioned above (Ikonomidis Svedmark and Nyberg, 2009).

Thus, while for some users, privacy is a disintegrating condition or state, seemingly impossible to protect, for many other users, privacy – in any traditional sense – has never been a perceived right or concern. In mediatized contexts, as Nissenbaum points out, "what people care most about is not

Figure 2 McKee and Porter's dimensions for informed consent, 2009.

simply restricting the flow of information but ensuring that it flows appropriately" (2010: Intro, para. 2). This is also supported by Boyd's discussions of youth and the emerging concept of private publics (2014). So to consider how we might protect participants, researchers may need to consider a different set of questions, such as: "What is a person's relationship to their information in this context?" or more specifically, even: "How does a person feel about his or her relationship to his or her information?" (Markham, 2012). These questions can be extended, of course, to larger groups or to discussions of data flow more broadly, as the case of the Havasupai tribe at the beginning of this article so vividly illustrates.

Informed Consent

This term poses many challenges in Internet-related research contexts. Emerging historically from ethical dilemmas of biomedical research, such as intravenous drug testing, the process of obtaining informed consent is designed to ensure that persons understand and accept the potential risks of research and willingly participate. This formulation is based on certain premises: first, it assumes that the researcher can literally see the potential participant to verify certain demographic information, such as age, socioeconomic status, or race that helps to determine whether or not the participant falls into a known category of vulnerability. Second, it assumes that procedures, purposes, and potential risks and benefits can be delimited and explained adequately. Both assumptions are faulty, but this history sustains a strong bias toward visual verification of 'informed,' 'consent,' and 'vulnerability.'

In Internet or digitally related research contexts, the objective of informed consent may be well intended but problematic. Researchers have sought and used robust and innovative approaches to online consent, and while no form of consent is perfect, consent in Internet research can raise particular issues. For example, is consent needed, and if so, How can we gain consent from anonymous chatroom or online forum participants? How can we ensure our participants do not fall into a vulnerable category? Where are waivers of consent appropriate in Internet research? What sort of protection should we afford information in large-scale digital databases, or, where are the human subjects in big data? These questions have compelled reconsideration of the goals and even the concept of informed consent. Many scholars such as Ikonomidis Svedmark and Nyberg (2009) provide good reasoning for why informed consent should not be an a priori (regulatory) requirement, but a (researcher) decision made based on the contingencies of the specific situation. Case studies illustrate how obtaining informed consent can cause harm, how informed consent is sometimes impossible, and how informed consent can be counterproductive. Svedmark's more recent work (2012) poignantly demonstrates that harm is – or should be – a more central consideration than informed consent.

In light of this, the AOIR ethics committee (Markham and Buchanan, 2012) suggests that researchers and ethical review boards can make stronger decisions about whether and how to obtain informed consent by returning to the rationale or premises for informed consent rather than taking for granted the regulatory norms for obtaining informed consent in a priori fashion. This stance would enable a more proactive role in determining how best – on a case-by-case basis – to enact beneficence, justice, and respect for persons. Notably, regulatory bodies are shifting more and more toward this stance. The National Science Foundation (2008) has extended guidelines to recognize and facilitate emergent, case-by-case considerations of informed consent. The U.S. Research Council is in the process of recommending significant changes to the way informed consent is conceptualized within the complexities of twenty-first-century information and data contexts (National Research Council, 2014). Additionally, research ethics boards are finding the flexibilities in the extant regulations to better match the fluid and synchronous mode of Internet communications, and also seeing more varied online consent models, including portals, virtual rooms, survey-type consents, and iterative consent.

The topic of informed consent continues to grow more complex as technologies and human social experience entangle with profit-minded stakeholders. Take, for example, the 2014 case of Facebook conducting mass manipulation of users' news feeds to conduct experiments on emotions. (A URL search for the Facebook emotional contagion study will yield a wide range of positions and reports on the topic and controversy. To view the original report, see Kramer et al. (2014).) Informed consent was not obtained, but was also not considered a relevant consideration. Users agreed to terms of service that allow for such manipulation. Significant public outcry is a powerful reminder that use of big data to conduct mass experiments on the digitally saturated public comes with ethical if not legal responsibility.

(Protection of) Personally Identifiable Information

Much of the discussion of privacy and ethics in the first decade of Internet research focused on protecting the privacy and anonymity of individuals and groups in online contexts. Now, at the end of the first decade of the twenty-first century, we face daunting challenges associated with data protection. As noted by the U.S. National Research Council (2014), "There is so much information that is freely and openly available about individuals that informational risk is ubiquitous in society. …. The issue of data protection spans the spectrum of methods and modes of inquiry in the social and behavioral sciences, whether qualitative or quantitative, longitudinal or experimental, observational or questionnaire-based, or micro- or macro-level or large-scale" (p. 83). As it gets easier to collect data in large-scale and automated ways, data and personally identifiable information become increasingly complicated categories. Archiving everyday deliberate activities, such as surfing patterns or demographic information, is commonplace. But it is also possible to collect nondeliberate activities such as backspacing and deleting. Programs can archive information passively or incidentally, as when a restaurant recommendation site not only tags but also stores one's geolocation, or when a self-tracking exercise device logs, statistically manages, and then archives one's physical data over time (sleep cycles, weight gain or loss, heart rate, running times, blood pressure, medication schedules, and so forth).

Snowden's (2013) revelation that the National Security Agency was secretly collecting personally identifiable information increased public awareness of the crumbling myth of data privacy. For research communities, too, this issue is

a growing ethical concern. While there is no consensus on how to handle and effectively protect personally identifiable information, the problem is recognized as a universal priority.

It is important to note that ethical issues continue to grow more complicated as new technologies and capacities develop. Although the above terms point to persistent concerns, others may emerge. Thus, it is important that ethical decision making remain active and case-based, rather than passive acceptance of or adherence to existing norms and parameters of regulatory bodies. This is an important shift in how regulators, policymakers, and research communities are talking about how ethical guidelines are best applied in actual research situations.

Provocations for Further Consideration

This article provides less direct guidance than questions or provocations to help guide thoughtful reflections. In this sense, this article aligns with a case-by-case or process-based approach to ethical decision making. This means more questions than answers.

In addition to suggesting that readers consult the ever-growing list of best practice guides, the following two principles may be useful: Ethical dilemmas are less visible from a distance, and harm or vulnerability can never be fully understood in advance. These two provocations confront Internet-specific considerations and serve as a rough summary of the past 20 years of shifting emphasis in the area of research ethics, based on the rise of computational power, storage capacity, and the ubiquitous characteristics of mobile and networked digital technologies.

Ethical Dilemmas Are Less Visible from a Distance

Some years ago, in an early draft of the AOIR ethics document, we suggested:

> As knowledge production becomes more dependent on information derived from some sort of Internet research, we recognize that the objects of scientific research are more person-based than not. This has become clear to our group over the past twenty years of Internet development. For instance, a researcher cannot talk about discursive or physical participation in the online information sphere without acknowledging that this necessarily involves a person somewhere in the process – a person who is thinking and behaving within his or her own cultural and moral stances. The Internet complicates the fundamental research ethics question of *personhood* (Is an avatar a person?) and *harm* (does the connection between data and persons or between an online identity and a real-life person enable psychological, economic, physical, harm?). Due to the complexity of Internet contexts, harm may not be immediately visible, but may emerge at any point in the research process.

One useful way of exploring the extent to which Internet texts or data sets might connect to persons is through what we might call the 'distance principle.' When the conceptual or experiential distance between the researcher and author/participant is close, we are more likely to naturally identify and frame the research scenario as one that involves 'humans' and therefore warrants ethical considerations of risks and potential harms. Arguably, as we work with aggregate data sets, separate texts from their original context, or use automated means of collecting, sorting, managing, and analyzing digital materials, the experiential or perceptual distance grows. As this happens, researchers may be more likely to define the research scenario as one that does not involve 'human,' simply because persons are no longer obviously present. This is most crudely illustrated when we compare an online interview through instant messaging with scraping data archives through an application programming interface and stripping this data of personally identifiable information.

In the latter, there is a greater possibility for forgetting that there was ever a person somewhere in the process that could be directly or indirectly impacted by the research. The distance principle can help one examine the role between the researcher and the researched. As the AOIR committee emphasizes, this sort of principle is not intended to establish the nature or extent of relevant ethical issues involved, but to simply help demonstrate that ethical issues are possibly present even if they are difficult to identify at that moment in time, or based on the technologies in use at that time. That is, ethical issues may be 'downstream' and only rise to the surface due to a change in Internet architecture, Internet norms, or even legal changes.

Harm or Vulnerability Can Never Be Understood in Advance

Although ethical guidelines were developed as a result of direct physical or psychological harm to persons participating in research studies, harm is discussed far less than those proposed methods for preventing it: informed consent and protecting privacy. While these latter terms are important, their regulatory construction often overshadows considerations of harm itself. This becomes evident when we look at counterintuitive examples of harm and vulnerability.

For example, Ikonomidis Svedmark and Nyberg (2009) studying blogging practices in Sweden wanted to publish excerpts from certain blogs for a publication. Based on typical regulatory interpretations of harm and vulnerability, they determined that a mother blogging intensively about the year prior to her daughter's suicide would be a vulnerable participant. They determined that an interior designer blogging about daily life and posting pictures of the family would not be considered a vulnerable person. The decision to base vulnerability on blog content is a sensible and common practice. Yet in this case, it mischaracterized both bloggers' feelings about their blogging activities. The mother of the suicide victim encouraged the researchers to post excerpts, name her directly, and point readers to her actual site. In other words, she did not want her confidentiality protected and she did not consider herself to be vulnerable. On the other hand, the interior designer was shocked and dismayed by the researchers' request and insisted that they not post any excerpts, photos, or other personally identifiable information about her blog. Potential vulnerability in this case could not be determined by using typical means of categorizing participants.

As our lives become more informational, potential harm can be more closely tied with considerations of how our personal information or personally identifiable information is being used outside the original context. As noted elsewhere (Markham, 2012):

> What may seem ephemeral or innocuous at one point in time might shift rapidly into something that causes real or perceived harm. Following information as it flows across multiple contexts, for example, may yield different assessments of privacy in each. For example, although I might willingly broadcast all my tweets to the public world at large, and would not mind my tweets being used in visual mapping of trends, I would feel violated to find all of my tweets – sent out in a sporadic fashion, in an ephemeral sense, or over a long period of time – combined together and analyzed by a researcher. Despite the fact that users recognize the overtly public nature of their presentation of self via digital media, this has no universally agreed upon or a priori correspondence with the harm that might eventually be felt.
>
> p. 4

As the terrains of research continue to shift along with new technologies, it behooves researchers to consider harm from a grounded, case-by-case perspective. This does not mean abandoning regulatory advice, but rather, paying attention to the intentions of these regulations. This involves at the very least interrogating the common (and often misleading) assumptions that harm is only connected to known categories of vulnerability, harm will be mitigated with informed consent, or that protecting privacy through confidentiality can prevent harm.

Shifting from Regulation-Based to Processes-Based Models

Across the globe, societies are experiencing significant flux and transformation in the way digital information is woven into and influences everyday life, workplace practices, social norms, and institutional structures. Likewise, all academic disciplines are challenged to make sense of these transformations in light of research practice. Actively confronting these challenges means not only being aware of them, but thoughtfully considering how we might better address these challenges.

This article has addressed the issue from a somewhat conservative perspective, focusing on the rights of participants and emphasizing the risks of current research practices. This is deliberately skewed, to urge researchers to assume a somewhat worst-case scenario approach (following the advice of pioneering Internet researcher Storm King in 1996). Certainly over the past 20 years, the landscape for what we might consider within the realm of ethical practice has shifted radically. We encourage a methodologically and disciplinarily sound approach for protecting research participants while engaging in the most productive of research endeavors.

Recommended Resources

For more information on ethics and research guidelines within the U.S. context, visit the Department of Health and Human Services Web site. This Web site offers an international compilation of human research standards (hhs.gov/ohrp/international/intlcompilation/intlcompilation.html). Notably, these conversations continue to change and grow. The information and data sharing capacities of the Internet have broadened discussions among a range of scientific and regulatory communities. The AOIR documents some of these discussions on their ethics wiki at ethics.aoir.org.

For more information on philosophical discussions of ethics within technological contexts or computing, see Buchanan's edited collection on virtual ethics (2004); Ess's work on *Digital Media Ethics* (2009); Moor's discussions of *Cyberethics* (2007); or Tavani's edited volume on *Ethics and Technology* (2013).

For more information on process-based models of ethical decision-making practices in digital contexts, see the AOIR ethics documents (2002, 2012); McKee and Porter's work on casuistic or case-based ethics (2009); Markham's discussions of ethics as method (2006); Wyatt's work on ethics in e-research (2011); or Nissenbaum's discussions of contextual integrity (2012).

For general overviews of Internet research ethics, see the AOIR ethics wiki, which links to the AOIR Ethics Committee guidelines as well as other resources. For an extensive review of key issues, see the entry by the same name in Stanford University's *Encyclopedia of Philosophy*: http://plato.stanford.edu/entries/ethics-internet-research/.

Intellectual property, copyright, and fair use are important ethical topics that were not addressed in this article. Copyright bridges legal and ethical realms. Conceptualizations, regulations, and laws vary by country. This is an important consideration in Internet research. Copyright and intellectual property may be a more relevant concern than the issue of human subjects in certain disciplines – i.e., linguistics. To get more information about these debates and best practices, see American University's Center for Media and Social Impact Web site, which contains an extensive section on fair use of copyrighted materials. For more information on copyright law by country, see http://en.wikipedia.org/wiki/Category:Copyright_law_by_country.

Interoception

André Schulz, University of Luxembourg, Walferdange, Luxembourg

Abstract

This article summarizes contemporary knowledge on the psychology of interoception, i.e., the perception of bodily processes, and the underlying physiological mechanisms. First, theoretical models of interoception are presented and brain regions are discussed, which may play a role for the processing of interoceptive neural signals. Second, the most relevant methods to assess interoceptive accuracy are described. Third, the relevance of interoception for disciplines of general psychology is outlined. Fourth, the role of interoceptive accuracy for the development and maintenance of symptoms in clinical mental disorders are presented. Finally, some future challenges in interoceptive research are discussed.

Introduction

Sensory information from the body originates from different sensory receptor types, which can be distinguished (Dworkin, 2007) into (1) exteroceptors (e.g., mechanoreceptors in the skin), (2) proprioceptors (e.g., receptors in the spindles of skeletal muscles), and (3) interoceptors (e.g., mechano-, chemo-, thermo-, or metaboreceptors in visceral organs). Exteroceptors process external sensory information, such as visual, auditory, or tactile stimuli. A limited number of body-internal macroevents, such as heartbeats, may also partially be processed via exteroceptive, i.e., somatosensory receptors. Information on body position, muscular movement or tension are relayed by proprioceptors. Sensory information indicating the state of visceral organs is considered to constitute interoception. There is a variety of receptor subtypes that are responsible for interoceptive signal processing. Every organ system has its own population of interoceptors. They can be categorized using the following characteristics: (1) their functionality; receptors may be sensitive to physical movement or pressure (mechano- or stretch receptors), to a chemical substance or a specific concentration of this substance (chemoreceptors), to an under- or overrun of a threshold of a certain temperature (thermoreceptors), or to the registration of a metabolic process (metaboreceptor). (2) Their sensory threshold; e.g., one population of baroreceptors in arterial blood vessels respond to blood pressure changes within a range up to 100 mmHg, while another one responds to changes over 100 mmHg. (3) Their adaptability; the timeframe, within which interoceptors adapt to continuous stimulation may vary in subpopulations (fast- vs slow-adapting). Sensory information from interoceptors is continuously transmitted to the central nervous system. The majority is relayed over reflex circuits in the spinal cord or the brainstem without any conscious perception of these processes. However, this interoceptive information can reach consciousness if a predefined range of 'normal' functioning is exceeded. For instance, when body temperature will reach 38 °C, it is perceived as fever, if the filling of the stomach is exceeded, it is perceived as nausea, or if heart rate and blood pressure dramatically increase in a stressful situation, it is perceived as aversive. Interoception research does not only focus on conscious perception of bodily processes, but it also aims to understand interoceptive signal processing below consciousness level. One objective of this article is to summarize psychological disciplines, in which the conscious or unconscious processing of interoceptive signals play a decisive role.

Neurophysiology and Neuropsychology of Interoception

The majority of afferent signals from interoceptors are transmitted over the Nervus vagus and the Nervus glossopharyngeus and then relayed over the nucleus tractus solitarius (NTS), the main sensory brainstem center for visceral-afferent information. Reflex circuits for the maintenance of homeostasis in physiological processes, such as blood pressure (i.e., arterial baroreflex), oxygen saturation, or body temperature, involve synapses within the NTS. The NTS is in close exchange with other medullary structures, the caudal (CVLM) and rostral ventromedial medulla (RVLM), and the dorsal motor nucleus of the vagus (DMNV), which all play a role in these reflex circuits. From the NTS afferent signals are projected onto midbrain areas (parabrachial nucleus, PBN; periaquaeductal gray, PAG). The PBN and PAG are connected with higher structures, involving the limbic system, hypothalamus and thalamus, as well as cortical regions. The conscious perception of bodily signals certainly requires the involvement of the thalamus as important relay for sensory information. Cortical areas that are responsible for the processing of interoceptive neural signals are the anterior cingulate cortex (ACC), the anterior insula (AI) in the temporal lobe, the somatomotor cortex (SMC), the somatosensory cortex (SSC), and the prefrontal cortex (PFC). Neuroimaging studies have shown that a heartbeat detection task activates the right AI, the ACC, and the SMC, whereas the gray matter volume in the AI correlates with the accuracy in such tasks (Critchley et al., 2004). The processing of interoceptive signals, such as heartbeats, may result in the generation of specific electrocortical potentials (e.g., heartbeat-evoked potentials). These potentials are located in the ACC, the right IA, the SSC, and the PFC (Pollatos et al., 2005), which play a role in interoceptive signal processing. In addition to the transmission of afferent neural signals over the cranial nerves, another pathway over the spinal cord may also play an important role in interoception, the lamina1-spinothalamocortical pathway (Craig, 2002). Projections over

 http://dx.doi.org/10.1016/B978-0-08-097086-8.14145-5

this pathway also reach the NTS and thalamic structures, but it also integrates other afferent information from the body, such as information on nociception and tissue damage.

Concepts of Interoception

There is an ongoing debate, which mechanisms in afferent signal processing from the body can be called 'interoception.' Given the importance of interoception for psychology, there is also a shortness on theoretical models to include different levels of interoceptive signal processing. Vaitl (1996) views interoception as a general term to be subdivided into somatosensory, proprioceptive, and visceroceptive subsystems. In his model of interoception, sensory information from all three subsystems is transmitted to the CNS, where their representations are processed. CNS representation may reach awareness if attention is focused on visceral sensations. Learning processes are assumed to be the consequence of conscious CNS representations and may influence subjective reports, behavior or evaluation and could further affect the previous levels of interoceptive signal processing. The assumption of this regulatory circuit is congruent with feed-forward models of somatosensory amplification. The integration of somatosensory, proprioceptive and visceroceptive afferent signals is well in line with models on interoception and emotion, which propose that the experience of emotions relies on afferent signals from different sources (Wiens, 2005). Each of the methods to assess interoception described below involve different components of interoception in Vaitl's model. Heartbeat-evoked potentials, for example, require the stimulation of interoceptors *and* CNS representation, while awareness, report, or learning are not necessary, while they would be for performance in heartbeat detection tasks. From the current point of view, afferent signal transmission represents an independent factor, as it has been repeatedly shown that interoceptive signal processing is deficient in individuals with degeneration of afferent autonomic nerves, while interoceptors are still intact (Leopold and Schandry, 2001; Schulz et al., 2009). Furthermore, CNS representations can be differentiated into brainstem representations and higher (cortical) representations.

The denomination of interoceptive measures has been extensively discussed in literature. Common terms are 'interoceptive awareness,' 'interoceptive sensitivity,' or 'interoceptive accuracy,' although they all describe the same kind of measure (here: accuracy in a heartbeat detection task). Garfinkel and Critchley (2013) have addressed this issue and postulated a hierarchical model of interoception. They understand 'interoceptive sensibility' as dispositional tendency to be internally focused and thus as a prerequisite for the successful completion of interoceptive tasks. In their words 'interoceptive sensitivity' should represent the objective accuracy in these tasks, whereas 'interoceptive awareness' could be understood as metacognitive measure that quantifies individuals' explicit knowledge of their interoceptive accuracy. Although this differentiation is plausible, the measure indexed by interoceptive tasks should be called 'interoceptive accuracy' instead, since this term is rather neutral. It does not suggest that a specific score reflects 'sensitivity' or 'awareness,' since some individuals may be hypersensitive, which leads to misinterpretation of signals and thus to lower accuracy, or others may focus a maximal grade of awareness toward interoceptive stimuli that may still be below the sensory threshold.

Methods to Assess Interoception

Heartbeat Detection Tasks

The majority of research is based on experimental paradigms, in which participants are requested to detect their heartbeats. They are further divided into heartbeat counting tasks and discrimination tasks. Heartbeat counting tasks were developed by Schandry (1981), who named the task 'mental tracking test.' The task consists of time intervals of different duration (original version: 35, 45, and 55 s), during which the participants are instructed to silently count the number of their heartbeats. This number is later compared with the actual number of heartbeats in this interval. The absolute value of the difference between both is divided by the actual number of heartbeats and this 'inaccuracy' index is then subtracted from 1, which results in the accuracy score of the heartbeat counting task. It has been repeatedly demonstrated that the accuracy score depends on the wording of the instruction given. The comparison between a standard instruction ("count all heartbeats you feel in the body") and a strict instruction ("count only those heartbeats about which you are sure") suggests that an individual's knowledge on their heart rate and capacity to accurately estimate the duration of time intervals may be important factors for the accuracy in heartbeat counting tasks (Ehlers and Breuer, 1996). Heartbeat discrimination tasks were originally developed by Brener and Jones (1974) and further elaborated by others. In these tasks participants are asked to judge whether a set of consecutive exteroceptive stimuli (e.g., lights, tones, tactile stimuli) appear simultaneously with their own heartbeats (S+ trials) or not (S− trials). The available variants of this task mainly differ in the setup of S− trials, since some present exteroceptive stimuli with a fixed delay to heartbeats, while others simulate a set of artificial stimuli without any relation to the actual heartbeats. In a systematic investigation on possible time delays between heartbeats and the elicitation of an exteroceptive signal it was demonstrated that the optimal delay for the concurrent perception of both is about 230 ms after an R-wave (Brener and Ring, 1995). Heartbeat detection is reduced in individuals with a degeneration of afferent autonomic nerves due to diabetes mellitus.

Heartbeat-Evoked Potentials

Heartbeat-evoked brain potentials (HEPs) represent electrocortical potentials, which are related to the perception of cardiac signals, such as heartbeats. HEPs can be measured 250–600 ms after a cardiac R-wave and have their largest amplitude over the right hemisphere at frontal and central sites. HEP amplitudes have been demonstrated to reflect an individuals' performance in heartbeat detection tasks, motivation to perform in those tasks, and attentional focus on heartbeats. Nevertheless, the conscious perception of heartbeats is not required to produce HEPs, since afferent signals from the cardiovascular system continuously reach higher cortical areas. As a consequence, HEPs are measured during heartbeat

detection tasks (Leopold and Schandry, 2001), during rest (Schulz et al., 2013b) or during another foreground task (Gray et al., 2007). HEPs are calculated as event-related potentials with the R-wave in the ECG as 'event.' Since it was demonstrated that up to a time delay of 450 ms the electrocardiac field of the ECG and the HEP are partially overlapping, both effects have to be disentangled (Gray et al., 2007). Again, HEPs are reduced in individuals with a degeneration of afferent autonomic nerves (Leopold and Schandry, 2001).

Visceral Modulation of Startle

Afferent signals from visceral organs have the potential to modulate higher central information processing. Initially, this relationship was investigated in the cardiovascular system. The additive stimulation or unloading of arterial baroreceptors by the cardiac cycle and an external pressure/suction device affects the human startle response to auditory stimuli, a defensive reflex that is relayed over the brainstem. Even without external stimulation startle responses are lower during the early cardiac cycle phase (R-wave + 230 ms) than during the late cardiac cycle phase (R + 530 ms), as are subjective intensity ratings of the startle stimuli. The difference of startle amplitudes during early and late cardiac cycle phase has been called 'Cardiac Modulation of Startle' (CMS) effect. This effect is also largely diminished in individuals with diabetic neuropathy (Schulz et al., 2009). The CMS effect, therefore, reflects baroafferent neural traffic from the cardiovascular system. In contrast to the other methods described, the CMS may serve as a methodology to estimate afferent neural signals relayed at the level of the brainstem, since only brainstem processes are involved (arterial baroreflex circuit, acoustic startle circuit). Furthermore, afferent signals from cardiopulmonary baroreceptors, the gastrointestinal system and the respiratory system may also influence the human startle response. Thus, the concept of CMS could eventually be extended to 'Visceral Modulation of Startle.' HEPs and CMS are considered psychophysiological indicators of interoceptive signal processing.

Factors Determining Accuracy in Interoception Tasks

Differential Aspects of Interoceptive Accuracy

A number of sociodemographic factors play a role in the accuracy in interoceptive tasks. In general, results suggest that men are more accurate in interoceptive tasks related to sensations of the cardiovascular, the respiratory or the gastrointestinal system than women. Possible explanations for these effects could be sex differences in vascular musculature or hemispheric lateralization, which also play a role in interoception. The higher proportion of body fat in women than in men could also account for these differences, as it has been shown that individuals with lower body fat perform better in heartbeat perception tasks, and accuracy in these tasks is negatively correlated with BMI (Herbert et al., 2013). Furthermore, Khalsa et al. (2009) have demonstrated that accuracy in heartbeat perception tasks and age show a negative association ($r = -.30$). This correlation could be explained by reduced sympathetic tone, decreased sensitivity of baroreceptors, or reduced arterial stiffness with increasing age. Contrary to common wisdom, experienced meditators do not show higher accuracy in interoceptive tasks (Khalsa et al., 2008), than normal controls, although they report subjectively increased awareness to bodily states.

Physiological Determinants

Arterial baroreceptors represent one important type of interoceptors, which are responsible for cardiac interoception. In response to head-up tilt or isometric exercise, accuracy in heartbeat detection tasks is highly correlated with stroke volume (SV; $r = .59$) and momentum ($r = .67$), which represents the product of SV and velocity of blood outflow (Schandry et al., 1993). Furthermore, accuracy in heartbeat detection is associated with the change in the pre-ejection period (PEP) and the cardiac output in response to a mental arithmetic stressor. It could thus be concluded that cardiodynamic parameters, which are considered reflecting inotropic activation (contractility), are positively associated with accuracy in heartbeat detection. Nevertheless, this relationship has not been consistently reported in the literature. Heartbeat perception accuracy is positively related to systolic blood pressure (SBP), but negatively related to heart rate. Typically, there is a negative relationship between heart rate (HR) and SV, except for conditions of extensive exercise or stress. Increased SV, decreased PEP, and increased SBP may generally induce higher stimulation of arterial baroreceptors. Psychophysiological parameters that imply increased stimulation of baroreceptors per single heartbeat are, therefore, positively correlated with accuracy in heartbeat detection tasks (SV↑, PEP↓, SBP↑), while parameters that imply decreased stimulation per heartbeat (HR) show the opposite pattern. Individuals with a high degree of physical training tend to have superior accuracy in heartbeat detection compared with nontrained individuals.

Interoception and Emotions

Early Concepts

In the original James-Lange theory of emotion, all emotional processes are understood as epiphenomena of visceral activation, which takes place when an individual is confronted with an emotionally relevant stimulus. Nevertheless, this theory has not been empirically supported. According to the modified theory by Cannon and Bard, visceral responses and the genesis of emotions are concurrently elicited through the perception of an emotionally relevant stimulus. Individuals with interrupted transmission of visceral-afferent signals, for example, still experience emotions, although visceral activation is too slow to match the genesis of emotions. In the seminal study by Schachter and Singer (1962) individuals received epinephrine, which drives the sympathetic nervous system, or a placebo substance. One subgroup of participants was informed about the 'adverse effects' of the substance, another subgroup was naïve. The authors observed that the informed group attributed their subjective level of arousal to the adverse effects of the drug, while the naïve participants reported a higher intensity of anger after being exposed to anger provocation by an experimenter. These results suggest that both the perception of bodily states and cognitive appraisal are important for the experience of an emotion.

Current Point of View

Contemporary theories do not assume interoceptive signals as crucial for the experience of emotions anymore. Nevertheless, individuals with spinal cord injury have been found to report reduced intensity of emotions, which suggests that afferent information of bodily states is important, but not a prerequisite for emotion genesis. Current concepts assume that interoceptive neural traffic reaches 'first order' central structures, such as the dorsal pontine areas, the AI, and the somatosensory cortex, which may be associated with a phenomenological level of emotional experience. In a 'second order' of central representation of interoceptive signals, structures such as the anterior cingulum integrate these genuine interoceptive signals and other sources of bodily information, e.g., somatosensory feedback and attention. Self-reported emotional experience may thus be the consequence of integrating interoceptive signals and other information of bodily states, as well as paying attention to these processes (Wiens, 2005). A large body of evidence indicates that a more intense experience of emotions is positively associated with accurate heartbeat perception. Neuroimaging studies suggest that the processing of interoceptive signals and the experience of emotion share neural structures, such as the AI, the ventromedial prefrontal cortex (VMPFC), and the ACC (Pollatos et al., 2007).

Interocepion and Decision Making

Damasio's Somatic Marker Hypothesis

The influential somatic marker hypothesis by Damasio (1994) postulates that interoceptive signals are regularly integrated into processes of decision making. In every context, in which decisions are expected to be made, the outcomes of possible action alternatives are anticipated. This anticipation produces a specific visceral response to be integrated in affective responses to the expected outcome. These responses, either transmitted over somatosensory or visceral-afferent circuits, are called 'somatic markers.' Damasio hypothesized that these 'somatic markers' shape decision making. The neural structure that is thought to be responsible for the integration and evaluation of somatic markers is the VMPFC. There is a large body of evidence supporting the somatic marker theory. In experimental research, human decision making is assessed through specific paradigms, such as the Iowa Gambling Task. Performance in this task is positively associated with sympathetic responses in anticipation of punishment or reward, putatively reflecting the availability of somatic markers, as well as with accuracy in interoceptive tasks. Patients with neurological damage in the VMPFC do not show comparable electrodermal responses to anticipated punishment or reward (Bechara et al., 1996). Dunn et al. (2006) provide a comprehensive review of the somatic marker hypothesis.

Interoception and Stress

Interoceptive Accuracy during and after Acute Laboratory Stressors

While interoception describes the transmission of ascending signals on the brain–body axis, stress represents a prominent example for descending information on the brain–body axis. Stress and activation drive the two physiological stress systems, the sympathetic–adrenomedullary (SAM) axis including the sympathetic nervous system, and the hypothalamus–pituitary–adrenocortical (HPA) axis with cortisol as final product. Neural and endocrine signaling resulting from the activation of both axes may change the activity of visceral organs (e.g., inotropic and chronotropic effects on the myocardium) and typical brain regions, which are responsible for their perception (e.g., thalamus, insular cortex). Thus it can be argued that interoception and stress are closely linked. Laboratory stress tests are designed to provide a stressful environment that guarantees for a maximal degree of standardization, ecological validity (i.e., cognitive, affective, and behavioral aspects of stress), and effectiveness. However, the direction of the effect of a laboratory stressor on interoceptive accuracy largely depends on the methods used to investigate interoception. Comparing both heartbeat detection tasks, these opposite effects were observed with a strong laboratory stressor, the Socially Evaluated Cold Pressor Test (SECPT) (Schulz et al., 2013a): Stress seems to increase interoceptive accuracy if attention is solely focused on visceral sensations (i.e., heartbeat counting), while it decreases if attention is additionally focused on exteroceptive stimuli (i.e., heartbeat discrimination). One possible conclusion is that stress effects on interoception depend on attentional processes.

Evidence on the impact of stress on psychophysiological indicators of interoceptive signal processing is sparse. Acute stress induced by an SECPT was found to change the pattern of the cardiac modulation of startle (Schulz et al., 2011). Two studies investigated the impact of acute laboratory stressors on heartbeat-evoked potentials. A moderate arithmetic stressor could not modulate the HEP amplitude per se, but the HEP was correlated with cardiac responses to the stressor (Gray et al., 2007). Acute pain during a mild version of the cold pressor test attenuated HEP amplitudes (Shao et al., 2011), but possible later effects or relationships to both stress axes were not reported.

Stress Hormones

Certain stress hormones are considered to play an important role in the processing of interoceptive signals. First, the activation of the autonomic nervous system may result in a release of catecholamines, such as epinephrine. Although catecholamines do not cross the blood–brain barrier and, therefore, cannot modulate the processing of interoceptive signals at the level of the CNS, epinephrine binds to beta1-adrenergic receptors at the myocardium. The binding of epinephrine to beta1-adrenoceptors causes positive inotropic (increased contractibility), chronotropic (increased heart rate), and dromotropic effects (faster depolarization), which lead to an increase of SV and a decrease of the PEP (Schachinger et al., 2001). It was repeatedly shown that cardiodynamic parameters, such as PEP or SV, are associated with the accuracy in heartbeat detection tasks (Schandry et al., 1993). It is likely that the increased stimulation of arterial baroreceptors caused by increased SV is responsible for this effect. Furthermore, peripheral sympathetic activation induced via beta1-adrenergic

agents and central sympathetic activity elicited by alpha1--adrenergic agents increases heartbeat perception accuracy (Moor et al., 2005). Second, cortisol, the final product of HPA axis activation, may also have the potential to modulate interoceptive signal processing. A dose of 4 mg of intravenously administered cortisol may induce higher heartbeat-evoked potentials in a state of high alertness compared with a state of low alertness (Schulz et al., 2013b). This effect may feed into a vicious circle of increased attentional focus on physical symptoms, increased anxiety and higher levels of cortisol, which may represent possible psychoneuroendocrine mechanism underlying psychological feed-forward models of somatosensory amplification. Interestingly, cortisol does not affect the cardiac modulation of startle, suggesting that this effect is limited to the cortical representation of interoceptive signals, but does not alter the brainstem processing of afferent bodily signals (Schulz et al., submitted). In contrast to catecholamines, cortisol crosses the blood–brain barrier and affects cells in the entire body, including the CNS. The described results can be attributed to activity in the thalamus, which represents a major relay center for exteroceptive and interoceptive sensory information, and was demonstrated to be affected by cortisol administration. The importance of the HPA axis for altered perception of physical sensations is further underlined by the fact that dysregulation of the HPA axis can be observed in many body-related mental disorders, such as somatoform disorders (Rief and Barsky, 2005) or depression (Terhaar et al., 2012).

Chronic Stress

There is very little research on chronic stress and interoception. This is surprising in view of the widely accepted notion that chronic stress exposure causes dysregulation of the SAM and the HPA axes, which in turn are of particular relevance for the above mentioned mental disorders. Clinical data suggests that these dysregulations contribute to the generation of physical symptoms and may thus disrupt the adequate processing of interoceptive signals (Rief and Barsky, 2005). Nevertheless, an association between self-reported chronic stress and interoceptive accuracy in laboratory paradigms has not been demonstrated, as yet (gastric stimulation: Rosenberger et al., 2009; heartbeat detection task: Schulz et al., 2013a). Both studies, however, assessed chronic stress in healthy participants. It remains for future studies to investigate possible abnormalities in interoceptive accuracy in chronically stressed individuals, which may already show SAM and HPA axes dysregulation.

Interoception in Learning and Memory

The model of stress and memory consolidation by McGaugh (2000) postulates that two physiological processes are crucial for the enhancement of memory consolidation after stress: (1) glucocorticoids (rodents: corticosterone; humans: cortisol) that bind on glucocorticoid receptors within the NTS, the locus coeruleus (LC), and the basolateral amygdala (BLA) and (2) peripherally circulating epinephrine, which cannot cross the blood–brain barrier, but activates visceral organs, whose afferent signals are transmitted to the NTS and LC. From these structures, over noradrenergic pathways, beta-adrenergic synapses in the BLA are activated, which induces the release of cyclic adenosine monophosphate (cAMP) and cAMP-dependent protein kinase. Both substances can enhance memory consolidation. Postsynaptic efficacy of beta-adrenergic synapses is increased by glucocorticoids. Results from animal models show that both processes, glucocorticoid secretion and afferent signal transmission from visceral organs, are necessary for memory consolidation. In humans, the increase of baroafferent neural feedback induced by norepinephrine-infusion improved long-term memory (Moor et al., 2005). Interoceptive neural signals, therefore, play an important role for the stress-induced improvement of memory consolidation in animals and humans.

Interoception in Mental Disorders

Panic Disorder

The most frequently investigated disorder in relation to interoception is panic disorder. In cognitive models of panic disorder it is assumed that panic patients have enhanced selective attention for threat-related stimuli in general and body-related cues in particular. This attentional bias may result in increased interoceptive accuracy. In concordance with this hypothesis, many empirical papers/articles found superior accuracy in heartbeat counting tasks in patients with panic disorder as compared with healthy individuals or other mental disorders (Ehlers and Breuer, 1996). A positive relationship between panic symptoms and interoceptive accuracy has also been observed in children (Eley et al., 2004). Cognitive-behavioral therapy of panic disorder does not change performance in heartbeat perception, but heartbeat perception negatively predicts the outcome of therapeutic intervention (Ehlers and Breuer, 1996). Nevertheless, there are also negative reports, and Willem Van Der Does et al. (2000) conclude from a re-analysis of the data of many of these studies that the majority of patients with panic disorder do not have generally increased accuracy, but only a minority. Moreover, higher accuracy in heartbeat counting tasks was only found when using the standard instruction ("count all heartbeats you feel in the body") and not in the strict instruction ("count only those heartbeats about which you are sure") (Ehlers and Breuer, 1996). This highlights the importance of knowledge about one's own heart rate in panic patients for performing this task, which may be more precise in panic patients, while healthy individuals tend to underestimate their heart rate in this task.

Depression

Affective disorders are often accompanied by autonomic dysregulations, which are also reflected in specific symptoms, such as the disruption of the sleep–wake cycle, dysregulation of appetite, sexual dysfunction, or psychomotor inhibition or agitation. It is plausible that the dysregulation of autonomic processes also induces alterations in the perception of phenomena that are autonomically controlled. Dunn et al. (2007) have reported that individuals with a mild depression may have reduced interoceptive accuracy, while individuals with a severe depression may not differ in their accuracy

from healthy controls. However, in this investigation it is unclear whether the difference between both depression groups is due to the severity of disease or to their use of medication, since the number and dosage of antidepressants was notably higher in the severe depression group. A reduction of interoceptive accuracy in major depression is also reflected in a decrease of heartbeat-evoked potentials as compared with healthy control individuals (Terhaar et al., 2012), which may be associated with altered activity in the insular cortex, which could be observed in depressed individuals. Since in a clinical setting there is a substantial overlap of depression and anxiety symptoms, it is not clear to what degree both components may differentially affect interoception. In a student sample it was demonstrated that there is a negative relationship between depression and interoceptive accuracy only in highly anxious individuals (Pollatos et al., 2009), which suggests the more important role of anxiety for interoception. Furthermore, it was reported that anxiety and anhedonia in a subclinical sample interact in that there is a positive relationship between anxiety and interoception only in individuals with low anhedonia (Dunn et al., 2010). Taken together, depressive symptomatology is associated with a tendency for decreased interoceptive accuracy, which may additionally be moderated by anxiety level.

Somatoform Disorders

The perception-filter model of somatoform disorders (SD) postulates that hyperactivation of the autonomic nervous system and the HPA axis contribute to increased perception of physical sensations in SD (Rief and Barsky, 2005). Study findings, however, are very mixed. This could be due to the heterogeneity of the conditions classified as SD, some of which emphasize the misperception of bodily signals (e.g., medically unexplained symptoms), while others focus more on medically unestablished health-oriented anxiety (e.g., hypochondria). Even within the field of medically unexplained symptoms (MUS) it is questionable whether individuals with complaints in different organ systems should be classified under the same condition (e.g., cardiovascular symptoms vs. chronic back pain). Furthermore, there is a debate in the literature on the expected direction of the difference between somatoform patients and controls. As summarized by Schaefer et al. (2012), some models assume an increased focus of attention on bodily processes in SD, which may lead to increased accuracy in interoception, while opposing models propose deficient processing of interoceptive signals in SD. Empirical data are in partial support of both hypotheses. On the one hand, Pollatos et al. (2011) found that a mixed group of somatoform patients showed lower accuracy in a heartbeat counting task than a healthy control group. On the other hand, high symptom reporters in the normal population as well as patients with MUS both show less accurate perception of CO_2 ratio in the air than healthy individuals (Bogaerts et al., 2010). Schaefer et al. (2012) reported that a mixed somatoform outpatient group and a matched healthy control group did not differ in the accuracy of the heartbeat counting or discrimination task. However, a negative correlation between the number of symptoms and the accuracy in the heartbeat counting task was observed. It can be summarized that there is a tendency to observe lower accuracy in interoceptive tasks in patients with MUS. Nevertheless, SD in general and MUS in particular may be characterized by an inappropriateness of processing afferent information from the body. It is questionable whether this deficiency is solely reflected by a quantitative reduction in interoceptive paradigms or if this alteration should not rather be seen as a qualitative change. Moreover, the role of possible dysregulated stress responses in SD, and the role of depression for altered interoception is still neglected in the current literature.

Eating Behavior and Eating Disorders

Patients with anorexia nervosa (AN), bulimia nervosa (BN), and binge eating disorder (BED) all report increased subjective awareness to bodily processes. In contrast, patients with AN and BN show lower interoceptive accuracy than healthy controls (Herbert and Pollatos, 2014; Pollatos et al., 2008), while there is no data on patients with BED. One challenge in interoception research with eating disorders is to determine which components of a putatively altered interoception may be attributed to the mental disorder and which may be a physiological and metabolic result of the dysregulated food intake. For instance, the increased interoceptive accuracy in obesity could be a result of an increase in arterial blood pressure. Furthermore, with a quasiexperimental approach of clinical group comparisons, it is impossible to disentangle cause and effect. There is empirical evidence supporting both alternative hypotheses. On the one hand, eating behavior has been experimentally manipulated to assess possible effects on interoception. Short-term fasting was found to increase accuracy in heartbeat counting tasks (Herbert et al., 2012), and the amplitude of heartbeat-evoked potentials (Schulz et al., 2014). While short-term food deprivation induces an increase in sympathetic tone, these effects are inverted in long-term food deprivation. It is, therefore, plausible that long-term fasting, such as observed in AN, may be a way of regulating the perception of bodily sensations. This assumption is also in line with the finding that AN patients show reduced interoceptive accuracy (Pollatos et al., 2008). On the other hand, interoceptive accuracy is positively associated with intuitive eating (Herbert et al., 2013), suggesting that high interoceptive accuracy contributes to healthy eating behavior.

Future Directions

In the majority of the studies described, interoception was operationalized using interoceptive tasks, e.g., heartbeat perception tasks, or psychophysiological indicators of interoceptive processing, e.g., heartbeat-evoked potentials. These studies demonstrate linear relationships between accuracy in interoceptive tasks or group comparisons in terms of 'higher than' or 'lower than.' A careful revision of the literature on stress and interoception, as well as interoception in mental disorders as compared with healthy controls demonstrates that the assumption of linear relationships does not hold. Future research should investigate more complex relationships between interoceptive measures and mental disorders, and also focus on qualitative instead of only quantitative changes in

interoceptive processing. Another challenge for future research lies in the assessment of different interoception modalities at a time with the same technique (horizontal integration), as well as different levels of the same interoceptive modality (e.g., signals at the level of the brainstem, the cortex, and subjective reports; vertical integration).

Interorganizational Relationships and Networks

Abstract

Research on interorganizational relationships and networks studies overall properties of relations between and among individuals, groups, or organizations, their antecedents, development processes, and outcomes. Focusing mainly on the organizational level, this article highlights why organizations forge different forms of relationships and what consequences result from the interorganizational links and the positions of organizations within their networks of relationships.

Interorganizational relationships refer to longer-term relationships between and among organizations (e.g., suppliers, customers, competitors, trade associations, and public sector organizations) that are pursuing a mutual interest while also remaining independent and autonomous, thus retaining separate interests. They can take a variety of forms, such as long-term sourcing agreements, partnerships, consortia, joint ventures, or alliances. Research on interorganizational relationships is concerned with properties and overall patterns of relations between and among organizations, their origins, the processes through which they are established, maintained, changed, and dissolved as well as with the consequences associated with such relationships (see Cropper et al., 2008). Interorganizational networks among individuals, groups, or organizations represent the overall patterns that evolve from, constitute, and foster such relationships (Knoke, 2012). All of the approaches in research on interorganizational relations and networks basically create their distinctive frames of enquiry from two core building blocks: a set of attributes describing the relating organizations and a set of attributes describing the nature of the relationships through which they are linked.

This article highlights why organizations forge different forms of relationships and what consequences result from the interorganizational links and the positions of organizations within their networks of relationships. Since it primarily concentrates on organization-level phenomena, it mainly highlights research that originates in, or has been adopted by, organization science. However, it should be noted that other disciplines have made significant contributions to our understanding of interorganizational relationships and networks, for instance, political science, economics, social psychology, economic geography, and legal studies. This article will highlight three major research traditions and their most important findings: first, the research tradition grounded in strategic management and organization science studying mainly bilateral relationships between organizations; second, the two research traditions devoted to interorganizational networks. Social network analysis is mainly founded in social psychology and sociology. The study of clusters organizations, i.e., local agglomerations of cospecialized firms and other institutions, primarily is based in economics, economic geography, and sociology. While the boundaries separating these research traditions lately seem to have become more permeable, as scholars mutually recognize and adopt concepts, methods, and research findings, the following sections will nevertheless discuss the three noted research traditions separately, as sufficient differences remain between them.

Interorganizational Relationships

The phenomenon of interorganizational collaboration is not new. Since the 1980s, however, one could witness in many industries a fast proliferation of joint ventures, alliances, consortia, and other forms of collaboration that has triggered a burgeoning literature. Among the prominent research questions addressed by this research are the following: Why do organizations engage in interorganizational cooperation, and when? With whom are organizations likely to ally, and why? How do organizations govern and manage their cooperative relationships? What are the outcomes and implications of particular forms of interorganizational relationships for the participating organizations and for third parties?

Motives

Actors' motives for engaging in interorganizational relationships can be quite varied (see Glaister and Buckley, 1996). Some firms cooperate in order to collude against common rivals or reduce competition by binding competitors as allies. Others use cooperation in an attempt to access needed resources and/or capabilities in order to enhance their competitiveness, e.g., in terms of improved products, better or wider market access, or faster market entry. Moreover, the formation of interorganizational relationships is seen as a means of fast, effective, and efficient learning, thus short-circuiting the process of acquiring and appropriating knowledge. In addition, cost savings in various ways can motivate the formation of interorganizational relationships. Through joint research, procurement, production, or marketing, firms strive to realize economies of scale and/or scope. Furthermore, firms can also cooperate in order to achieve specialization benefits, when they decide not to engage in the full spectrum of a particular product's value chain but to specialize in particular stages of production, and then to cooperate in the provision of the final product. A better information flow and improved coordination of resource flows among cooperating firms can also lead to cost and time savings. Finally, reduction of risk and uncertainty represent motives for forming interorganizational relationships when organizations seek to spread financial or other risks, for

example, when shouldering (mostly large) innovations or other projects (Nohria and Eccles, 1992).

Forms of Interorganizational Relationships

There exists considerable variation in the formal and informal structure of interorganizational relationships. Research has suggested numerous and diverging conceptualizations and measurements in order to capture this variety. Perhaps the most widely used conceptualization refers to the contractual and organizational arrangements by which collaborating firms govern their relationship. Specifically, different forms of collaboration are distinguished on the basis of the distribution of ownership- and decision-rights between the parties, and the coordination mechanisms employed in the relationship. In this vein, research distinguishes more hierarchical, hybrid and more marketlike forms of governance (Ebers, 1997; *see* Hierarchies and Markets). Other conceptualizations focus on the collaborators' motives, the types of resource interdependencies that exist between the collaborating organizations, or on the norms, rules, and processes that characterize the collaboration.

Consequences of Interorganizational Relationships

Depending on the specific rationale and design of a relationship, interorganizational collaboration may have implications for a number of organizational outcomes. Most prominently, research has studied how through their interorganizational relationships organizations enhance their innovativeness through mutual learning, augment their resource base and capabilities through privileged access to their partners' knowledge and resources, enhance their reputation through association with reputed partners, or improve their cost position through better coordination of interdependencies and production cost savings (Oliver, 2009). However, as a consequence of collaborating, firms may also experience an erosion of their competitive position by imitating or faster-learning partners. Moreover, lock-in effects of collaboration may impede necessary adjustments due to partner-specific investments and limited access to new information. In addition, a number of studies have addressed indirectly some consequences of interorganizational relationships by studying the stability and termination of interorganizational relationships (Doz and Hamel, 1998).

Theoretical Approaches and Methods

As in the field of organization studies as a whole, research examining when, why, how, and to what effects organizations engage in interorganizational relationships has employed a number of different approaches and theories. Most prominently, these include resource dependence theory, organizational economics, evolutionary theory, industrial marketing and purchasing, strategic management, neo-institutional theory, critical perspectives, and the management perspective theory.

Resource dependence theory views interorganizational relations as a means for securing needed resources and of enhancing control over resource supply. Power relations and the effective management of resource dependencies are at the center of researchers' interest. Organizational economics approaches, mostly informed by agency or transaction cost theory (*see* Transaction Costs and Property Rights), offer comparative assessments of various forms of interorganizational relationships. These stress the economizing effects of particular arrangements that result from an alignment of particular transaction and actor attributes with contractual and organizational features of the relationship. Evolutionary theory approaches seek to explain processes of boundary emergence, maintenance, shift, and erosion around interorganizational relationships. It analyzes interorganizational relationships through the generic conceptual scheme of variation, selection, and retention (Carroll and Hannan, 2000). Industrial marketing and purchasing approaches, often with regard to technological collaboration, study how the resource, informational and social interdependencies that exist between the collaborating organizations impact on their behavior (Håkansson and Snehota, 1995). Scholars from the field of strategic management focus on the exchange and allocation of resources and information within interorganizational relationships, and on how interorganizational relationships can be utilized for improving a firm's conduct and profitability (Jarillo, 1993). Neo-institutional theory, by contrast, studies how legitimacy pressures, social institutions, and institutionalized behaviors shape the forms and functioning of interorganizational relationships (Strang and Sine, 2002). Critical perspectives on interorganizational relations highlight how divergent interests and asymmetrical power relations among organizations, including the political use of language, shape interorganizational relations and influence their outcomes (Hardy and Phillips, 1998). The management perspective on interorganizational relationships focuses on the series of processes undertaken by a team of individuals, with various skills and capabilities, that shape both the direction to be taken by the collaborating organizations and the allocation and implementation of resources toward those ends (Huxham and Vangen, 2005).

With regard to methods employed, case study and survey research dominate the study of interorganizational relationships. Longitudinal studies are still rather rare, as are experiments and simulations.

Interorganizational Networks: Social Network Analysis

Social network analysis views interorganizational networks as a set of linkages (e.g., resource, friendship, informational ties) among a set of actors (individuals, groups, or organizations). Social network analysis offers various algorithms designed to describe and analyze positions of nodes within, and structural properties of, interorganizational networks. The basic aim of this research tradition is to understand how the overall structure of an interorganizational network, and an actor's position within that network, provides opportunities and constraints for actors' behavior (*see* Network Analysis). Compared to research on interorganizational relationships, this strand of research thus tends to pay more attention to the overall embeddedness of organizational and individual actors in networks of relationships than to individual attributes of the actors and of their individual relations.

Social network analysis suggests two broad ways in which overall structural features of social networks influence actors' behavior. First, particular network structures and positions have implications for the information that is available to actors and thus shape their decision-making and behavior. Second, particular network structures and positions in various ways invest actors with, or deprive them of, power to exert control over other actors. Such power may stem, for example, from utilizing informational advantages, privileged access to other actors, invoking obligations associated with particular relations, or from being able to mobilize sanctions by third parties (see Burt, 1992).

Principal Methods of Network Analysis

Simulation and experiment represent important methods within social network analysis. However, more and more social network analysts have begun to complement these traditional methods with survey research and sometimes ethnographic analysis. Important concepts that have been explored include network and actor centrality (i.e., measures of the connectedness of actors within a network); measures concerning structural properties of networks such as the density of a network (indicating the number of established ties in relation to the possible ties among the actors in a network); and the concept of clique (denoting a subset of actors within a network all, or most, of whom are directly tied to one another); or similarity measures: for instance, structural equivalence (two actors occupy structurally equivalent positions if they entertain identical linkages with the same third parties in the network) (see Wasserman and Faust, 1994).

Major Research Subjects

Prior to the 1980s, the bulk of research in social network analysis concentrated on developing and analyzing mathematical models of social structures and ensuing behaviors. Since then, however, there has been a proliferation of studies that apply these models to empirical phenomena (see Grabher and Powell, 2004). Two issues in particular have received considerable attention: interlocking directorates and social capital.

Interlocking Directorates

This research studies how the composition of firms' boards of directors influences firm behavior. If firms' directors sit on the boards of other firms, the directors of which in turn sit on the boards of other firms, this creates interlocking directorates. There exist several competing views as to the role that such interlocks play. However, many scholars suggest that interlocks represent an indicator of social relations among organizations, and of the extent to which firms are integrated into particular networks. Research has shown that interlocking directorates influence, for example, the diffusion of practices, executive pay, the use of 'greenmail' and of 'golden parachutes' policies for top management, the prevalence of structural defenses against takeover attempts, participation in mergers and acquisitions, and other elements of firm strategy such as the extent of research and development and the form of firm financing (see Mizruchi, 1996).

Social Capital

The notion of social capital originates from community studies that highlighted the role of strong, intense personal relationships among the members of a local community that invested them with mutual trust and the power for collective action. Social capital endows actors with a credential that entitles them to credit, and with a resource that can be utilized in action. At least two competing conceptualizations of social capital can be distinguished. A structural view sees social capital as a function of the information and control advantages that an actor enjoys who is in a broker position between otherwise unconnected actors; this position exploits a 'structural hole' in a network (Burt, 1997). A relational view sees social capital as a function of the intensity and extensiveness of personal bonds among actors. In this perspective, strong ties among actors, intense relationships characterized by mutual trust, a sense of obligation, common norms, and expectations, create social capital on which the respective actors can draw (Coleman, 1990).

In examining the consequences of social capital, research has identified two main effects. First, social capital can be utilized for increasing the efficiency of action through increasing the efficacy of information diffusion. Strong ties and intense relationships among actors that share many characteristics make information exchange easier and less ambiguous; likewise, exploiting the position of a structural hole enables a more efficient diffusion of information, because redundant contacts are minimized. Second, social capital can be utilized as a productive resource that enhances actors' goal achievement. This can be realized, for instance, by exploiting the position of a structural hole for learning about, and exercising control over, more rewarding opportunities, for instance, with regard to career advancement or firm profit. Likewise, in densely connected networks characterized by strong ties among actors, information about actors' behavior is disseminated quickly and evaluated on the basis of similar norms; thus, behavior can readily be socially sanctioned, cooperation is enabled, and opportunism constrained. Interorganizational networks whose members command significant relational social capital were thus found to thrive and prosper.

Interorganizational Networks: Clusters of Organizations

It has long been a well-known phenomenon that firms are not evenly distributed in geographic space but to a greater or lesser extent cluster locally. From the streets and quarters occupied by specialized trades in medieval towns, to the diamond-cutting industry of Antwerp and Tel Aviv; the coal and steel industry in the Ruhr, Lothringia, and Silesia regions; the cutlery industry in Sheffield and Solingen; the financial services industry in London and New York City; to the software industry in California's Silicon Valley, firms during different periods of time have formed regional or local clusters. While regional interorganizational networks thus by no means are a novel

phenomenon, research interest in regional interorganizational networks since its inception in the late 1800s (Marshall, 1920) has experienced a revival beginning in the 1980s.

The Formation of Clusters

The literature identifies two broad reasons why firms, together with some supporting organizations, cluster regionally or locally. First, through clustering firms can realize agglomeration economies. These result from both urbanization advantages and localization advantages. Urbanization advantages include economies of scale with regard to a shared infrastructure (e.g., for communication or transport), economies of scope (e.g., technological spillovers and informational externalities), specialization benefits (leading to technological or skill advantages), and transaction cost savings (e.g., reduced search costs for buyers and suppliers) (Krugman, 1995). Localization benefits comprise most importantly easy access to locally concentrated resource inputs (e.g., raw materials, specialized skills, specific attitudes of a local workforce, or colocated suppliers). A related line of reasoning stresses that clustering among firms is enabled and supported by regionally embedded institutions such as chambers of commerce, employers' unions, banks, science parks, universities, and training centers. These institutions often provide important resources, e.g., capital or access to distribution channels and potential customers. Moreover, they often act as informational brokers that support the exchange of information among firms, encourage and facilitate mutual learning, and can thus foster the responsiveness, adaptability, and innovativeness of networked firms.

Second, relational advantages emanating from the business and social relationships among geographically concentrated firms and individuals can also foster clustering. Vigorous competition from nearby competitors and face-to-face contact with demanding local customers can put pressure on the competitiveness and innovativeness of firms. Frequent contact with employees from rival firms and their products can further mutual learning. Family and friendship ties among local business people, common membership in local trade associations, sports clubs, and political institutions can be a source of knowledge and learning and provide better access to resources, e.g., capital and political influence that are required for successful business development. Moreover, intense social ties, behavioral norms, and routines may smooth cooperation, enable the exchange of tacit knowledge, encourage a ready and more trustworthy exchange of information among network members, and may thus support mutual learning and innovation (Porter, 1990).

Outcomes of Local Clusters

In line with these driving forces, research has identified a number of consequences associated with regional clusters of firms. Perhaps the most widely debated outcome concerns the increased competitiveness of regional cluster firms. Two major driving forces can be identified. On the one hand, clusters enhance competition through intense competitive pressure from nearby rivals and customers; this puts high pressure on firms and their employees to compete. On the other hand, localization and relational benefits provide competitive advantage over nonclustered rivals.

A second theme widely discussed in the literature concerns learning and innovation advantages. Local proximity and shared norms and traditions are said to allow for better cooperation even among rival firms, and to promote technology and informational spillovers. Together with competitive pressure, this can contribute to enhanced incentives as well as opportunities for learning and innovation. In addition, it is noted that clusters of small cospecialized firms that can flexibly recombine their resources and capabilities can be lighter on their feet than larger, more integrated competitors. Collectively, these firms are therefore said to be able to adapt more quickly to changes in demand, both quantitatively and qualitatively (Piore and Sabel, 1984).

Both postulated effects make regional clusters a favored theme in discourses on regional economic development. Endogenous growth and development of regions as well as sustained regional competitiveness are among the promises that have been associated with regional clusters (Staber et al., 1996).

However, there is evidence from research that the above-noted effects of regional clusters can, but need not necessarily, arise. There exist numerous examples of clusters that thrived at one point in time, only to fail later. Many coal and steel regions in the USA and Western Europe have shared this fate, as has the once admired minicomputer cluster along Route 128 in Massachusetts, USA. Several factors may contribute to the decline of regional clusters. Some of these are inherent to the functioning of regional clusters, some associated with external developments. They include the following: failing demand for a cluster's product, obsolescence of particular modes of production, competition from similar clusters in other regions, loss of the ability to coordinate cospecialized activities, and inertia due to a loss of developmental abilities. As this debate about the consequences of regional clusters for the participating firms and their respective regions shows, performance evaluations of business networks and regional districts are extremely difficult and problematic.

Methods and Approaches

Most research to date builds on case study evidence. A large number of conceptual studies engage in transferring more general insights from particular disciplines, for instance, economics or sociology, to the field of regional clusters.

At the end of the nineteenth century, economics was among the first disciplines to analyze the phenomenon of regional clusters. Paradoxically, the increasing globalization in the 1980s revived interest in internationally competitive, regional clusters, both in economics and economic geography (Porter, 1990; Krugman, 1995). Evolutionary economics developed a particular interest for the learning and innovation characteristics of regional clusters (Nooteboom, 2000) that is also shared by the innovative milieu approach (Maillat, 1991). Industrial sociology analyzed regional networks employing the labels of industrial districts and new industrial spaces (Storper, 1997). Institutional theory sociologists emphasized the social and institutional structures underlying regional clusters (Herrigel, 1996).

Conclusion

Over the last decades, interorganizational relationships and networks have become considerably more prominent in both practice and research. Pertinent studies have mainly emphasized the benefits that organizations experience when participating in various forms of supraorganizational structures, yet also noted a few risks. As interorganizational relationships and networks are scrutinized by many disciplines focusing on different phenomena, applying different theories and methods, this field of study has been characterized as a being fragmented into different silos of research. While silo'ing offers benefits of specialization, it makes it difficult to accumulate findings across silos. However, as some research in the field is beginning to demonstrate, there exist potentially fruitful opportunities for enhanced dialogue across extant research silos, be they constituted by different disciplines, theoretical lenses, or study objects (Cropper et al., 2011). The resulting cross-fertilization could contribute to an enrichment of our understanding, as well as a consolidation of empirical findings and theoretical conclusions, concerning why, when, and how different kinds of relationships and network structures within and among organizations have which effects on organizational and higher-level outcomes.

Abstract

This encyclopedia article reviews the major predictors of interpersonal attraction, the desire to be around and form a friendship or romantic relationship with another person. The main predictors include physical attractiveness, desirable personality traits, similarity, familiarity, and reciprocal liking. Other factors that facilitate or limit these effects, as well as situational and extradyadic influences, are also discussed. Finally, findings related to each of these predictors are tied together under the overarching frameworks of social exchange theory and sexual strategies (evolutionary) theory.

Interpersonal attraction refers to the desire to be around and form a friendship or romantic relationship with another. This encyclopedia article reviews the literature on interpersonal attraction, discussing main findings and underlying processes, as well as facilitating and limiting conditions of its major determinants.

Physical Attractiveness

Not surprisingly, people like others who are good-looking. Research on heterosexual romantic attraction shows that people like, talk more to, are friendlier toward, and request more dates from those who are physically attractive (Walster et al., 1966). This preference exists across cultures (Buss and Schmitt, 1993) and for both sexes. Men express a greater emphasis on the physical attractiveness of potential mates than women do, but interestingly, women's implicit (i.e., not consciously recognized) preferences for physical attractiveness (as assessed with response time and date requests) are just as strong as that of men (Eastwick et al., 2011). Research indicates that looks are also important in nonromantic attraction, finding that people are more interested in potential friends who are attractive (Black, 1974). So, the liking for attractive others is quite robust, transcending gender, culture, and relationship type.

From an evolutionary perspective, people like good-looking mates because they contribute to the viability of one's offspring. One reason for this is that physically attractive people are healthier in some ways, suggesting that the preference for good-looking mates represents an attempt to find high-quality genes with which to mix one's own. For example, facial and bodily symmetry is attractive and is also associated with good health (Perilloux et al., 2010). Second, the physical features that men and women find attractive in the opposite sex correspond with the differential sexual strategies that each sex uses to augment the viability of their genes in future generations. Men, who have low minimal costs in reproduction, can have many offspring and invest little in each; they therefore prefer physical indicators of fertility in women such as youthful features and a 0.7 waist-to-hip ratio (Furnham et al., 2005; Jones, 1995). Women, who have higher minimal costs in reproduction, invest more in the survival and success of a few offspring and are therefore tuned to physical indicators (signs of status, such as a large jaw and prominent forehead; Rhodes, 2006) that a man can provide resources for the offspring.

In addition to augmenting this evolutionary explanation for heterosexual romantic attraction, a social perspective can also explain homosexual romantic and general/friendship attraction. First, being physically attractive carries social benefits, not only for oneself, but also for one's romantic partner and friends. For example, men received more favorable evaluations when they were with an attractive versus unattractive woman (Sigall and Landy, 1973), and both sexes were seen as more attractive and credible when they had attractive friends (Walther et al., 2008).

Additionally, people tend to assume a whole host of good qualities about attractive people, including that they are nicer, more successful, have better marriages, and are happier in general. This "what is beautiful is good" bias (Dion et al., 1972) may be true to some small extent; for example, when participants had a phone conversation with a target (who they could not see), they rated the physically attractive targets as more likable and socially skillful (Goldman and Lewis, 1977). The question, then, is whether these desirable attributes are inherent in physically attractive people or result from receiving preferential treatment based solely on looks. One line of research supports the latter explanation. Specifically, when judges believed that they were talking with an attractive (versus unattractive) opposite sex target, both conversation partners were warmer and more animated regardless of the target's actual attractiveness (Synder et al., 1977; Andersen and Bem, 1981). Therefore, the "what is beautiful is good" bias seems to be at least partially a self-fulfilling prophecy.

Desirable Personality

Although not as extensively studied as physical attractiveness, personality is also important for attraction. One way in which personality affects attraction is through physical attractiveness: when one is told that a target has desirable personality traits, one views them as more physically attractive, but the opposite occurs when the target has undesirable personality traits (Lewandowski et al., 2007). Personality also influences attraction directly: across genders, everyone prefers potential mates

and friends who are kind, intelligent, honest, and dependable (Anderson, 1968; Buss and Barnes, 1986).

Similarity, Differences, and Ideal Self-Attraction

Similarity

Consistently, a large body of research has supported the notion that "birds of a feather flock together," showing that people are attracted to those whom they see as having similar attitudes to oneself (e.g., Byrne et al., 1970). Most of this work used the 'bogus other' technique, in which participants read responses to an attitude questionnaire (researchers gave certain responses to vary the degree of similarity to participant responses) and rated their liking for the respondent. Using another research paradigm, people also like partners with whom they are matched on maximal similarity after in-person interactions (Black, 1974; Byrne et al., 1970). Established couples are also more similar to each other in various ways (not just attitudes) than random strangers. This preference for similar others is not restricted to romantic attraction and is just as strong in friendship attraction (Black, 1974).

There are reasons that similarity is important for attraction. On the individual level, similar others validate and reinforce one's values and beliefs, which make the person feel good about these aspects of the self and provide a sense of stability (Byrne and Clore, 1970). On the dyadic level, people get along better with others who share their attitudes, values, and background (Davis, 1981), possibly because shared worldviews ease communication and diminish conflict. Additionally, people expect similar others to like them more than nonsimilar ones (Condon and Crano, 1988), which encourages them to reciprocate this perceived attraction (we discuss 'reciprocal liking' in more detail, later in this article). Taking these together, similarity may ultimately serve to increase the probability that initial attraction will lead to successful relationship formation (Aron et al., 2006).

Another line of research has examined factors that affect the strength of the similarity-attraction effect. A robust finding is that similarity is most important for values, beliefs, attitudes, and interests; findings for a similarity effect of personality have been much weaker and less consistent (Simpson and Harris, 1994). Additionally, central aspects of the self are more important in the similarity-attraction effect than peripheral self-aspects (Clore and Baldridge, 1968). Finally, this effect disappears when the other shares an aspect of the self that one dislikes (Novak and Lerner, 1968) – this makes sense considering that this kind of interpersonal similarity would reinforce and remind people of their unwanted aspects.

It is important to note that it is perceptions of, rather than actual, similarity that drives this effect. Previous studies that matched real people based on similarity confounded perceived and actual similarity, since partners knew about this matching criterion. Studies separating these variables have found that perceived similarity indeed predicts attraction better than actual similarity (Tidwell et al., 2013; Montoya et al., 2008). These variables are distinguishable because there are motivational processes and social schema that affect perceptions of similarity, especially at this nascent stage of relationship formation when people are still becoming familiar with each other. For example, people tend to assume that others are similar to themselves until they have reasons to believe otherwise (Rosenbaum, 1986) and they perceive physically attractive others as more similar to themselves than unattractive ones (Marks et al., 1981).

Differences and Self-Expansion

According to Aron et al. (2013), people are motivated to increase their potential efficacy by acquiring new content (i.e., resources, perspectives, and identities) for the self and thereby expand the sense of who they are. One important source of this self-expansion is close relationships. Specifically, people include close others into their own sense of self and thereby behave, feel, and think, to some extent, as though the other's self-content were actually their own. When the close other differs from oneself, one can incorporate new resources, perspectives, and identities that he or she did not previously possess. So, the self-expansion model predicts that people like different others who can provide self-expansion, which contradicts the robust findings that interpersonal similarity (in the attitude and background domains) is desirable. Resolving this contradiction, recall that similarity's function is to aid in relationship formation; thus, if another factor performs this function, would one prefer differences to capitalize on its self-expanding benefits? Indeed, when told that a reliable matching algorithm indicated that they would get along well, participants preferred a bogus other with different (rather than similar) interests (Aron et al., 2006).

Ideal Self

Another, albeit small, line of research has looked at the idea that people like others who resemble their own ideal self (the person one wants to become). Studies that have separated the effects of the actual versus ideal self have favored the latter. These effects were found for romantic (Klohnen and Luo, 2003) and general attraction (Wetzel and Insko, 1982) toward bogus others as well as in established friendships (LaPrelle et al., 1990; Thompson and Nishimura, 1952). One explanation for this ideal-attraction effect comes from the Michelangelo phenomenon (Rusbult et al., 2009), an effect whereby close partners support each other's goal pursuits (by modeling, reinforcing, and prompting desired behaviors) and thereby move each other toward their respective ideal selves. Given that partners resembling one's ideal self perform better in this role (Rusbult et al., 2009), liking these individuals represents an attempt to best engage the Michelangelo phenomenon and enjoy its self and dyadic benefits.

An extension of the self-expansion model attempts to consolidate the roles of ideal-similarity with those of actual similarity and differences in attraction. According to Zhou et al. (2008), people wish to expand toward their ideal self, acquiring resources, perspectives, and identities that are ideal-consistent. So, where the actual and ideal selves are disparate, one would prefer different others because they offer coveted self-aspects that the individual lacks. However, on self-aspects where the actual and ideal selves are close, one would prefer similar others to reinforce this desired proximity. Again, research on the ideal self's role in attraction is nascent, and

should be taken as speculative and a promising direction for future research.

Reciprocal Liking (Liking People Who Like You)

Another influential idea is that people like others who like them. Research on reciprocal liking has indeed found that people like others more when told that the other likes them, versus when no given information or when told that the other dislikes them (Backman and Secord, 1959). This effect exists for romantic as well as nonromantic attraction and also extends to intergroup attraction (Curtis and Miller, 1986; Lowe and Goldstein, 1970).

There are several reasons that people reciprocate others' liking for them. First, it decreases the probability of rejection and increases the belief that this other will be a source of pleasant interactions. Although these factors are themselves motivating, they also (like interpersonal similarity) increase the probability of successful relationship formation. Another explanation for reciprocal liking comes from balance theory (Heider, 1958), which states that one is motivated to maintain consistency among one's attitudes toward the self, other, and an object. In the case of reciprocal liking, the self is also the object, so if both one and the other like the self, one is motivated to also like the other to create or maintain the desired consistency.

Most research into the facilitators and limitations of reciprocal liking has been in the romantic domain. First, speed-dating studies suggest that reciprocal liking is restricted to people who like oneself uniquely, as opposed to those who like everyone (Eastwick et al., 2007). The strength of reciprocal liking also increases with the target's physical attractiveness (Greitemeyer, 2010). Interestingly, some evidence suggests that reciprocal liking peaks at moderate levels of other-liking and wanes beyond that. This may be because moderate other-liking adequately staves off rejection concerns and simultaneously creates some uncertainty that encourages thinking about the target (Whitchurch et al., 2011). Another relevant idea is gain–loss theory (Aronson and Linder, 1965), which proposes that reciprocal liking is generally stronger if the other went from disliking to liking oneself, rather than if the other liked oneself all along. The appeal of the former case may come from interpreting that the attitude change represents a successful attempt at 'winning the other over.'

Familiarity

Another major determinant of attraction is familiarity, the idea that one likes others to the extent that one has spent time with and knows them. This increase in attraction, interestingly, occurs even when interactions are superficial or passive and in the absence of any information about the target. For example, this effect emerged when participants' only exposure to the target was that she sat in their class (without talking to anyone); students liked her more when she attended class more frequently (Moreland and Beach, 1992). This effect also occurs when repeatedly viewing a stranger's photograph, even when it is presented subliminally (Bornstein et al., 1987; Zajonc, 1968). The familiarity-attraction effect is a specific application of Zajonc's mere exposure effect, the idea that simple exposure to any stimulus can increase liking for it.

Related to the familiarity effect is the propinquity effect, the idea that people like those who are physically close to them. Whether this proximity refers to how close someone sits to them in class or how close someone lives to them, the effect is robust and can be explained by the increased frequency at which people who are physically proximate see each other (i.e., repeated exposure).

Given that familiarity is an important factor in interpersonal attraction, a surprisingly little amount of work has gone into exploring its intricacies. (Much more work has been done on the overarching idea of mere exposure, but that work has generally not used social stimuli, and so will not be discussed here.) The most likely reason for this effect is that, in the absence of other information, familiarity signals that a person is safe. This is likely because, having lived in small groups during our ancestral past, humans were in close proximity to and frequently saw other people with whom they were interdependent. Therefore, throughout evolutionary history, familiarity and propinquity may have developed as signals of the trust and camaraderie associated with the in-group. Of course, it is likely that subsets of group members disliked and merely tolerated each other, making repeated exposure increasingly more discomfiting rather than pleasant. Indeed, one limit to this effect is that exposure needs to be at least neutral, and repeated exposure in unpleasant contexts can decrease liking (Perlman and Oskamp, 1971).

Situational Influences on Interpersonal Attraction

So far, the discussion has centered on determinants that are inherent in the dyad. However, there are also extradyadic and situational factors that can increase one's attraction to a target. For example, after seeing pictures of highly attractive women, men rated other women and even their own romantic partners as less physically attractive than did men who viewed images of average-looking women (Kenrick et al., 1989). A similar effect exists for women: after seeing highly dominant men, women are less satisfied with their own romantic relationships (Kenrick et al., 1994).

Another situational influence is the 'closing time effect,' which refers to the tendency for singles to perceive opposite-sex bar and nightclub patrons as more attractive as closing time nears (Pennebaker et al., 1979; Madey et al., 1996). The explanation of this effect comes from Commodity Theory (Brock, 1968), which states that the value of a resource increases with its scarcity. Indeed, as the night draws to a close and patrons are about to leave, potential partners become more scarce and thus more attractive.

Another factor is the influence of arousal on attraction, whereby romantic or sexual attraction can come from physiological arousal caused by an external source (Foster et al., 1998). This idea is based on Schachter and Singer's (1962) notion that emotions result from interpretations of physiological arousal. Specifically, when one becomes aroused, he or she searches the environment to locate the cause of this arousal and then uses this information to identify the particular emotion they are feeling. For example, arousal can be

experienced as fear (if a lion is running toward you) or as attraction (if an appropriate romantic target is nearby). In applying this idea, Dutton and Aron (1974) proposed specifically that arousal from one source may be misinterpreted as romantic/sexual attraction if (1) an appropriate target is close by and (2) the true source of the arousal is not immediately obvious. Indeed, their study found that men were more attracted to a female research assistant while they crossed a shaky bridge over a high canyon (which was presumably anxiety-inducing and physiologically arousing) rather than a stable bridge over a low rivulet.

Another idea is that the opinions of same-sex peers (or competitors) influence one's own perceptions of opposite-sex targets. When female participants see another woman smiling at a man, they find him more attractive than if the woman looked at him with a neutral expression (Jones et al., 2007). Furthermore, in a speed-dating study, both men and women were more attracted to potential partners if they saw that other people were romantically interested in these targets (Place et al., 2010). The influence of peers also extends to negative evaluations: knowing that other women found a man unattractive caused female participants to decrease their attraction toward this target (Graziano et al., 1993).

Conclusions

This encyclopedia article has reviewed several determinants of interpersonal attraction, including physical attractiveness, desirable personality traits, similarity, differences, ideal self, reciprocity, familiarity, and several extradyadic factors. As summarized here, many of these predictors of attraction, each with unique moderators and underlying motivations, tie together nicely into the overarching frameworks of social exchange and evolutionary theory.

Social exchange theory, the idea that people view relationships in economic terms of exchanging rewards and costs (Thibaut and Kelley, 1959), neatly ties together the major predictors of attraction. This is because, as previously discussed, selecting relationship partners using these criteria proffers certain psychological and social benefits. In sum, one likes similar others because they validate and reinforce the self, whereas one likes different others because they offer opportunities for self-expansion. People also like others who are ideal-consistent because they help move the self toward its ideal and familiar others because they signal safety. People also like others who like them because it boosts self-esteem and achieves a desired balance in attitudes. It is also important to remember that relationships are costly, requiring (material and psychological) resources and putting one at risk for rejection. Therefore, according to social exchange theory, interpersonal attraction is a function of the net gains versus losses that one perceives the target is likely to provide.

The evolutionary perspective of sexual strategies theory (Buss and Schmitt, 1993) also explains many of these findings. Physical attractiveness strongly predicts interpersonal attraction because it signals the ability to produce healthy offspring. Kindness and loyalty are important because people with these traits make good spouses and parents for one's future offspring. Throughout much of human history, people lived together in small tribal groups and knew one another; thus, similarity and familiarity may indicate that the person 'belongs to our group' and can provide safety and security. Ultimately, all romantic attraction serves the evolutionary purpose of obtaining the best mate possible for reproduction and parenting of offspring that will survive and successfully carry on one's genes.

Abstract

Interpersonal psychotherapy (IPT) is a brief, time-limited treatment that was originally developed for the treatment of major depression. IPT is derived from theories in which interpersonal function is recognized as a critical factor in psychological adjustment and well-being. IPT is also based on empirical research connecting change in the social environment to the onset and maintenance of depression. Although the initial goal of IPT is to reduce symptoms of depression, the major goal is to improve the quality of the patient's current interpersonal relations and social functioning. IPT moves through three defined phases, each of which is associated with specific strategies and tasks for the therapist and patient. Its well-defined and unique treatment strategies are aimed at resolving problems within four social domains: grief, interpersonal role disputes, role transitions, and interpersonal deficits. IPT has been found to be efficacious for major depression and has also been successfully adapted to treat other types of mood and nonmood disorders (e.g., eating disorders and anxiety disorders). In this article, IPT's development, treatment phases and strategies, therapeutic stance, and outcome research are described. In addition, areas in need of further research are delineated.

Introduction

Interpersonal psychotherapy (IPT) is a brief, time-limited therapy that was developed in the late 1960s by Klerman and colleagues, and then, in 1984, was indicated for the treatment of depression in a manual by Klerman, Weissman, Rounsaville, and Chevron (Weissman et al., 2000). IPT was derived from theories in which interpersonal functioning is recognized as a critical factor in psychological adjustment and well-being. IPT is also based on empirical research connecting change in the social environment to the onset and maintenance of depression (Paykel et al., 1969). The objective of IPT is to improve the quality of patients' current interpersonal relations and social functioning, which in turn reduces symptoms of depression. IPT was initially formulated not as a novel therapy, but as a descriptive attempt to represent the current practice of psychotherapy for depression (Klerman and Weissman, 1993). IPT makes no assumptions about the causes of depression but instead takes into consideration any genetic and biological, psychological, and social factors that predispose, precipitate, and perpetuate the disorder (Ravitz et al., 2013b). Moreover, IPT assumes that the development of clinical depression occurs in a social and interpersonal context and that the onset, response to treatment, and outcomes are influenced by the interpersonal relations between the depressed patient and significant others.

IPT moves through three defined phases, each of which is associated with specific strategies and tasks for the therapist and patient. Its well-defined and unique treatment strategies are aimed at resolving problems within four social domains: grief, interpersonal role disputes, role transitions, and interpersonal deficits.

IPT has been found to be efficacious for major depression and has also been successfully adapted to treat other types of mental disorders. In this article, IPT's development, treatment phases and strategies, therapeutic stance, and outcome research are described. In addition, areas in need of further research are delineated. The extensive empirical background and theoretical foundation, including the strategies and techniques of IPT, are fully described in a comprehensive book (Weissman et al., 2000).

Development

Adolf Meyer's (1957) theory that psychopathology is a result of maladaptive adjustment to the social environment lays the groundwork for IPT. Harry Stack Sullivan (1953) stands as the theorist who most clearly articulated the interpersonal paradigm and popularized the term 'interpersonal' as a balance to the then-dominant intrapsychic approach. Sullivan believed that psychiatry involves the scientific study of people and the processes that go on among them; accordingly, the unit of clinical study is the patient's interpersonal relationships, as people cannot be understood in isolation from them. In his theory, Sullivan (1953: 13) posited that people have "relatively enduring patterns of recurrent interpersonal situations," which can either foster self-esteem or result in hopelessness, anxiety, and psychopathology.

Sullivan developed a comprehensive theory of the connections between psychiatric disorders and interpersonal relations for the developing child in the family and for the adult in the multiple transactions of life. The roles of major interest to IPT occur within the nuclear family (as parent, child, sibling, partner); the extended family; the friendship group; the work situation (as supervisor, supervisee, or peer); and the neighborhood or community. The interpersonal approach views the relationship between social roles and psychopathology as occurring in two ways: disturbances in social roles can serve as antecedents for psychopathology; and mental illness can produce impairments in the individual's capacity to perform social roles. IPT is also associated with the work of John Bowlby (1982), the originator of attachment theory, who acknowledged the importance of early attachment to subsequent interpersonal relationships and psychopathology. In sum, IPT is derived from theories in which interpersonal functioning is

recognized as a critical component of psychological adjustment and well-being.

IPT is based not only on theory, but also on empirical research linking change in the social environment to the onset and maintenance of depression. Considerable research supports the key interpersonal problem areas. For example, people become depressed in the circumstances of grief, marital disputes, and the life changes associated with interpersonal role transitions, particularly in the absence of social ties. Moreover, longitudinal studies show that not only can life events trigger depression, but indeed depression can also trigger adverse life events (for a review see Frank and Spanier, 1995; Weissman et al., 2000). In combination, these data provide strong support for use of an interpersonal approach for the understanding and treatment of depression.

Depression is conceptualized as having three component processes: symptom function, social and interpersonal relations, and personality and character problems. Symptom function entails the development of depressive affect and the neurovegetative signs and symptoms (e.g., low energy, sleep and appetite disturbance), both of which are believed to be precipitated by biological and psychological factors. Social and interpersonal relations entail interactions in social roles with other persons derived from learning based on childhood experiences, concurrent social reinforcement, and personal mastery and competence. Personality and character problems refer to enduring traits such as inhibited expression of anger or guilt, poor psychological communication with significant others, and difficulty with self-esteem. These traits determine a person's reactions to interpersonal experience. IPT intervenes in symptom formation and social dysfunction associated with depression, rather than enduring aspects of personality, because of its relatively short duration and low level of psychotherapeutic intensity. There is little expectation that IPT will have a pronounced effect upon personality structure; however, many IPT patients do acquire new social abilities that may help offset personality difficulties. An important component of IPT for depression is the deliberate avoidance of issues related to personality functioning during the treatment of the acute symptomatic episode (Weissman et al., 2000).

The methods and techniques of many schools of psychotherapy share common ground (Frank, 1973), including attempts to help patients gain a sense of mastery and reduce social isolation. A major difference among the therapies lies in their conceptualization of the causes of the patient's problems, and in the typical length and focus of treatment. For instance, IPT differs from traditional psychodynamic approaches in that it is time-limited, focused, examines current rather than past relationships, and recognizes but does not focus on intrapsychic defense mechanisms and internal conflicts. Furthermore, IPT differs from cognitive and behavioral approaches in that maladaptive thoughts and behaviors are addressed only as they apply to problematic interpersonal relationships. The goal is to change the relationship pattern rather than associated depressive cognitions, which are acknowledged in IPT as depressive symptoms. Although the therapeutic style is less directive in IPT than in cognitive and behavioral approaches (i.e., less didactic/prescriptive), the therapies are similar in terms of their active current focus on specified target areas. In contradistinction to other psychotherapies, IPT recognizes but does not directly focus on the patient's personality characteristics.

Treatment Phases, Goals, and Strategies

The initial phase, ordinarily the first one to three sessions, includes diagnostic assessment and psychiatric history and establishes the context for the treatment. After a standardized diagnostic symptom review is conducted, the patient is diagnosed as depressed and assigned the 'sick role.' Patients are given the 'sick role' to exempt them from additional social pressures, increase their awareness of the need for help, and elicit their cooperation in the process of recovery. A detailed examination of the patient's interpersonal history (the interpersonal inventory) is conducted, which includes a review of the patient's current social functioning and current close relationships, their patterns and mutual expectations. During this review, changes in relationships are illuminated that were proximal to the onset of symptoms (e.g., the death of a significant other, changing to a new job, increasing marital discord, or disconnection from a friend). The interpersonal inventory provides a structure for elucidating the social and interpersonal context of the onset and maintenance of depressive symptoms and delineates the focus of treatment.

An evaluation of need for medication is based on the severity of symptoms, previous experience with medications, and patient preference. The therapist and patient then discuss the diagnosis and what the patient might expect from treatment. Symptom relief starts with helping the patient understand that the vague and uncomfortable symptoms are a part of a known syndrome, which responds to several treatments and has good prognosis. The therapist then links the depressive syndrome to one of four interpersonal problem areas: grief, role transitions, interpersonal role disputes, or interpersonal deficits. After the major interpersonal problem area is identified, the therapist makes a specific treatment plan with the patient to work on this problem area.

During the intermediate phase of treatment, typically the middle 7–11 sessions, the therapist implements treatment strategies that are specific to the identified problem area. *Grief* is identified as the problem area when the onset of the patient's symptoms is associated with the death of a loved one, either recent or past. The goals for treating grief include facilitating mourning and helping the patient to find new activities and relationships to substitute for the loss. *Role transition* includes any difficulties resulting from a change in life status (e.g., divorce, retirement or change in one's work role, moving, leaving home, diagnosis of medical illness). The patient is helped to deal with the change by recognizing positive and negative aspects of the new role they are assuming, and pros and cons of the old role this replaces. *Interpersonal role disputes* are conflicts with a significant other (e.g., a partner, other family member, coworker, or close friend), which emerge from differences in expectations about the relationship. The therapist assists the patient to identify the nature of the dispute and generates options to resolve it. If resolution is impossible, the therapist assists the patient in dissolving the relationship and in mourning its loss. *Interpersonal deficits* include patients who are socially isolated or who are in chronically unfulfilling

relationships. The goal is to reduce the patient's social isolation by helping to enhance the quality of existing relationships and encouraging the formation of new relationships. The problem area may change during the course of treatment. If the patient has several related problem areas, the therapist selects the problem area that is most prominent or likely to result in change.

In the termination phase of treatment, typically the last three sessions, the therapist assists the patient in evaluating and consolidating gains, acknowledging the feelings associated with termination, detailing plans for maintaining improvements in the identified interpersonal problem area(s), and outlining remaining work. Patients are also encouraged to identify early warning signs (e.g., low energy) and to identify plans of action at signs of relapse.

Throughout IPT, focus stays on the interpersonal context of a patient's life. For example, if a patient is having depressive symptoms, the therapist will focus on relationship difficulties that exacerbate the symptoms. Meetings should not pass without reference to the interpersonal goals, as they are unique and require specific and directive interventions by the therapist. Indeed, the therapist's ability to maintain focus on interpersonal themes has been associated with better outcomes (Frank et al., 1991). In session, unfocused discussions are redirected to the key interpersonal issues, and abstract and general discussions are minimized in order to preserve focus. Therapists refrain from making inquiries that evoke vague or passive responses, such as general questions about the patient's week. Rather, sessions begin with questions such as 'What would you like to work on today?' and 'How have things been since we last met?' These questions provide more direction for patients and focus them on recent interpersonal events and recent mood, which the therapist attempts to connect. Patients who describe problem areas will be asked about recent mood and other depressive symptoms in relation to interpersonal events; alternatively, if the patient focuses on symptoms, the therapist asks about recent life events and interactions (Weissman et al., 2000).

Therapeutic Stance and Techniques

Each model of psychotherapy can be characterized in part by the positioning of the therapist in terms of the nature of the relationship with the patient and the level of therapeutic activity. The IPT therapeutic stance is one of warmth, support, and empathy. The IPT therapist is active and advocates for the patient rather than remaining neutral. Moreover, the therapeutic relationship is not viewed as a manifestation of transference, nor is it to be treated as a friendship. Some of the most frequently used techniques include exploratory techniques, encouragement of affect, clarification, and communication analysis; other techniques include use of therapeutic relationship, behavior change techniques, and adjunctive techniques.

In addition to the traditional individual format, IPT can also be delivered in groups, known as interpersonal psychotherapy for group (IPT-G) (Wilfley et al., 2000). There is one 2 hour pretreatment meeting at the start of treatment; during this session, the interpersonal inventory is administered, problem areas are identified, and treatment goals are established. In addition, there is a mid-treatment individual meeting to review treatment goals and a posttreatment individual meeting to review changes made and strategize about ways to maintain treatment gains. The rationale for utilizing a group is that it serves as an 'interpersonal laboratory' in which there are multiple opportunities to practice one's interpersonal skills so that skills can be readily applied to outside relationships. In addition, the group setting breaks patterns of social isolation and stigma, while providing a supportive environment. Moreover, IPT administered in a group setting is a more cost-effective treatment modality than individual sessions.

The key elements of IPT-G are similar to traditional IPT in that it is time-limited, semistructured, and focused on changing interpersonal relationships. Groups typically include 7–9 members who are homogeneous with regard to diagnosis and heterogeneous with regard to interactional style.

Outcome Research

Research has demonstrated outcome and efficacy for IPT in the following domains: mood disorders (i.e., recurrent depression (Weissman et al., 2000), bipolar mood disorder (Frank et al., 2005), and major depression (Weissman et al., 2000)); eating disorders (i.e., bulimia nervosa (Fairburn et al., 1995; Nevonen and Broberg, 2006), binge eating disorder (Wilson et al., 2010), anorexia nervosa (Carter et al., 2011), and subclinical eating disorders (Nevonen and Broberg, 2005)); anxiety disorders (i.e., post traumatic stress disorder (PTSD; Markowitz et al., 2009), body dysmorphic disorder (BDD; Weissman et al., 2000), and social anxiety disorder (SAD; Bohn et al., 2013)); as well as other disorders (i.e., multisomatoform disorders (Sattel et al., 2012) and borderline personality disorder (Bellino et al., 2010)).

Interpersonal Psychotherapy for Group

IPT-G has been shown to be efficacious in adults for a number of disorders, including major depressive disorder (Bolton et al., 2013), comorbid depression and substance use disorder among female prisoners (Johnson and Zlotnick, 2008), PTSD (Krupnick et al., 2008), perinatal depression (Reay, 2013), bulimia nervosa (Nevonen and Broberg, 2006), binge eating disorder (Wilfley et al., 2002), and eating disorders not otherwise specified (Nevonen and Broberg, 2005).

Adaptations of IPT

IPT has been adapted for various populations, including depressed older adults (Miller and Reynolds, 2007), Hispanic populations (Markowitz et al., 2009), adolescents with mood disorders (IPT Adolescent Skills Training; IPT-AST; Young et al., 2010), adolescents with depression who engage in nonsuicidal self-injury (Jacobson and Mufson, 2012), couples (Weissman et al., 2000), women who are pregnant (Grote et al., 2009) or women who are experiencing postpartum depression (O'Hara et al., 2000), and patients with comorbid medical conditions (e.g., patients infected with human immunodeficiency virus; Ransom et al., 2008; Weissman et al., 2000).

New adaptations to IPT currently under pilot study are partner-assisted IPT for the treatment of perinatal depression (Brandon et al., 2012), IPT for adolescents with learning disabilities (adapted from IPT-A; Brunstein-Klomek et al., 2013), clinician-managed IPT (CM-IPT; O'Hara and Stuart 2013), and interpersonal and social rhythm therapy (IPSRT) used as monotherapy for the acute treatment of bipolar II depression (Swartz et al., 2009). IPT has also been adapted for women with depression and chronic pain (Poleshuck et al., 2010). IPT for the prevention of excessive weight gain has been piloted in adolescent girls (Tanofsky-Kraff et al., 2010) and is currently being evaluated in a large-scale randomized controlled trial.

IPT has been modified for brief delivery (Swartz et al., 2008), long-term delivery (Weissman et al., 2000), as a maintenance intervention following weekly delivery (Frank et al., 2007), and for use as adjunctive self-help (Weissman et al., 2000). IPT has been modified for delivery via telephone (Ransom et al., 2008) and in primary care settings (Peeters et al., 2013).

IPT has been translated into several languages (Markowitz et al., 2009; Weissman et al., 2000). Together, these findings indicate that IPT is not only an effective and promising treatment for a range of psychiatric disorders, but it also has the potential for widespread dissemination (Markowitz and Weissman, 2004).

Future Directions

Treatment Efficacy

Though IPT has been shown to be efficacious for several mental disorders, no study has determined the optimal duration or dosing of treatment delivery. A critical next step is to determine the optimal treatment length and dosing of IPT for particular disorders. Cuijpers et al. (2013) suggest longer treatment lengths do not produce better outcomes and may be associated with negative treatment outcome. The authors propose using a greater number of treatment sessions per week over a shorter treatment length (Cuijpers et al., 2013). In contrast, Weissman and Verdeli (2012) propose a model of three sessions IPT followed by a triaging component (e.g., monthly phone calls) based on patients' symptom severity. In cases where patients have improved but still endorse moderate symptoms and impairment, additional treatment sessions can be conducted. Therefore, continued research to investigate optimal timing, duration, and frequency of treatment delivery is needed.

Mediators and Moderators

Although a number of outcome studies in IPT document its efficacy, little is known about the mechanisms by which IPT exerts its effects (Frank and Spanier, 1995). A greater understanding of the mechanisms by which change occurs in IPT would assist in further refinements of the treatment and may yield insights about the nature of the psychiatric syndrome under investigation. Continued research to evaluate the efficacy of IPT with specific patient subgroups is needed. For example, Chui et al. (2007) found an ethnicity by treatment effect for the reduction of objective binge eating episodes among patients with bulimia nervosa. Specifically, African-American participants, compared to other racial/ethnic groups, showed greater reductions in binge eating episodes when treated with IPT than cognitive behavioral therapy (CBT) (Chui et al., 2007). Wilson et al. (2010) demonstrated specificity of treatment effects in that individuals with low self-esteem and greater eating psychopathology performed best in IPT at 2-year follow-up compared to those receiving behavioral weight loss and CBT-guided self-help. Thus, considerations to adapt IPT for particular patient subgroups may need to be employed to increase the overall effectiveness and applicability of IPT.

Widespread Dissemination of IPT

IPT was developed as a research intervention but still has not been well disseminated among clinicians (Weissman et al., 2000). Evidence-based psychotherapies are being deployed in primary care worldwide, and there is a continued need to integrate mental health services into primary care in the United States (Weissman, 2013). Substantial evidence exists that clients are not receiving evidence-based treatments, such as IPT, in routine clinical care (Wilfley et al., 2002; Wilson et al., 2010). Furthermore, even when clients do receive IPT, it is often not delivered competently (Weissman et al., 2006). Additionally, a limited number of clinicians have been proficiently trained to use IPT (Weissman et al., 2006).

Practical, cost-effective methods of training clinicians to implement IPT are urgently needed. For example, increasing training during residency programs may be beneficial, because, over the course of training, residents became more comfortable with using evidence-based treatments as first-line interventions; this approach has been used for the success implementation of IPT in psychiatry resident programs (Lichtmacher et al., 2006). To increase the dissemination and sustainability of training, alternative strategies that extend traditional training techniques (e.g., in-person workshops, which require substantial time and resources) may be of benefit. The 'train-the-trainer' approach may be a more sustainable training strategy than traditional training techniques. In this approach, an internal champion is trained in evidence-based care delivery, and then trains other clinicians in their setting (Fairburn and Cooper, 2011). Continuing education in evidence-based psychotherapies is an underused strategy for addressing gaps in training in underserviced communities. A program of four peer-led weekly courses on the fundamentals of evidence-based care demonstrated that participants favored the peer-led group format over self-directed learning, which may facilitate increased treatment implementation (Ravitz et al., 2013a).

It may also be helpful to explore the use of Internet-based methods for disseminating IPT. Online programs for clinical training are more cost-effective and scalable than in-person approaches (Fairburn and Cooper, 2011). Online training can be offered to geographically dispersed trainees using minimal person-based resources. Trainees can view material on their own time, increasing the acceptability of this approach. Additionally, trainees are able to go back and review material already learned, which can reinforce session content. Training can be readily updated to efficiently disseminate new information and materials. Consequently, online training overcomes many of the barriers to in-person training and thus has

strong potential to increase the number of therapists trained to deliver evidence-based interventions.

Conclusion

IPT is a specialty, time-limited treatment that has demonstrated efficacy for the treatment of many mental disorders in individual and group formats. The IPT model assumes that social problems produce an environment in which disorders are created and sustained; thus, IPT targets current interpersonal problems in the areas of interpersonal deficits, interpersonal role disputes, role transitions, and grief, in order to reduce disorder symptomatology. The widespread dissemination of this highly acceptable, evidence-based treatment is greatly needed to increase access to care.

Interpersonal Trust across the Lifespan

Ken J Rotenberg, School of Psychology, Keele University, Staffordshire, UK

© 2015 Elsevier Ltd. All rights reserved.

This article is a revision of the previous edition article by K.J. Rotenberg, volume 11, pp. 7866–7868, © 2001, Elsevier Ltd.

Abstract

The article outlines the development of trust across the life span. The development comprises: (1) honesty-trusting behavior toward caregivers during infancy; (2) honesty and reliability cognitive-based trust during early childhood; (3) honesty, reliability, and emotional trust distinctly in peers during middle childhood; (4) moral/abstract trust including social networks during adolescence; (5) romantic relationship and workplace trust during early adulthood; and (6) care provision and inheritance concerns trust during late adulthood and old age, respectively. Research shows that (1) trust beliefs during childhood longitudinally predict psychosocial functioning and (2) children who hold very high trust beliefs show elevated psychosocial problems.

The importance of trust and the development of trust are recognized in criminology, sociology, psychology, political science, and industry/organization among other disciplines (see Rotenberg, 2010). An EBSCO/PSYINFO search using the combination of psychology and sociology with the term 'trust' in the abstract yields a total of 112 345 publications across history. Of those, 2714 are publications within the last 6 months of July 2014, which shows that there are approximately 452 publications on trust per month. The current volume of research examining trust is indeed 'staggering.'

I provided a developmental outline of changes in interpersonal trust in the first edition, which was guided by the bases × domains × target dimensions trust framework (BDT; Rotenberg, 1994). This article will expand upon that proposal drawing upon current research. In addition, this article will deal with the related issues of: (1) whether or not childhood trust has 'consequences' for their psychosocial functioning across the life span, and (2) whether or not children who hold very high trust beliefs are at risk for psychosocial problems.

A Theoretical Framework

The BDT framework (Rotenberg, 2010) is now composed of three bases (reliability, honesty, and emotional) × three domains (cognitive/affective, behavior-dependant, and behavior-enacting) × two target dimensions (specificity and familiarity). The three bases of trust are: (1) reliability, which refers to the fulfillment of word or promise; (2) emotional trust, which refers to the reliance on others to refrain from causing emotional harm, such as being receptive to disclosures, maintaining confidentiality of them, refraining from criticism, and avoiding acts that elicit embarrassment; and (3) honesty, which refers to telling the truth and engaging in behaviors that are guided by benign rather than malicious intent and by genuine rather than manipulative strategies.

The three domains of the BDT comprise: (1) cognitive/affect, which entails individuals' beliefs and feelings that others demonstrate the three bases of trust (e.g., believes that others keeps promises); (2) behavior-dependent trust, which entails individuals behaviorally relying on others to act in a trusting fashion as per the three bases of trust (e.g., depends on another to keep a promise); and (3) behavior-enacting trust, which entails individuals behaviorally engaging in the three bases of trust (e.g., keeps promises). The term 'trust beliefs' will be used to describe the cognitive-affect domain and term 'trustworthiness' will be use to describe the behavior-enacting domain for ease of expression. The BDT framework includes the specificity dimension of the target of trust (ranging from general category versus a specific person) and familiarity of the target of trust (ranging from slightly familiar to highly familiar). According to the BDT framework, trust is the result of reciprocal processes whereby individuals demonstrate matching patterns of trust and establish a common social history.

The following developmental pattern was proposed. During infancy, trust is primarily composed of behavior-dependent honesty that is directed toward caregivers and strangers. During early childhood, children establish honesty and reliability cognitive trust that is manifested in behavior, which are directed toward a growing network of peers and adults. During middle childhood, the honesty, reliability, and emotional bases of trust are evidenced in interactions with adults, in peer relationships, and academic achievement that is linked to their reasoning about violations of social expectations and moral principles. During adolescence, all bases and domains of trust are extended to social-political events, moral issues in society, and sexual matters. Trust during early and middle adulthood becomes focused on romantic partners, and superiors and coworkers in the workplace. Finally, trust during later adulthood and very old age is focused on vulnerability to criminal acts, whether others will provide care, family members' inheritance claims, and whether the trust placed in family members or mankind will be confirmed after death. The proposed developmental pattern is formulated as a description of the *principal* basis and focus of trust at different age periods across the life span.

This article will address two additional issues: First, it addresses the extent to which psychosocial functioning across the life span is a consequence of childhood trust. Second, it addresses the question regarding whether or not children who hold very high trust beliefs are at risk for psychosocial problems?

Trust Across the Life Span

Infancy (0–2 Years)

During this period, individuals (1) form a sense of trust versus mistrust (Erikson, 1963); (2) establish different qualities of attachment with caregivers that include a sense of trust in them as represented in an internal working model (IWM) (Cohn, 1990; Lieberman, 1977; Dwyer, 2005; Sakai, 2010); (3) establish an IWM that affects subsequent social relationships; and (4) demonstrate shyness, which entails a low trusting orientation toward unfamiliar others. The primary form of trust during this period is behavior-dependent honesty, which is the tendency for infants to behavioral rely on care providers and others predicated on the *feeling* (i.e., affect) that their actions are guided by benign intentions.

Early Childhood (2–6 Years)

Trust during early childhood entails honesty as cognitive/affective basis of trust, behavior-dependent trust, and trustworthiness. This proposition has received support by the research by Harris and his colleagues (Chen et al., 2013; Corriveau and Harris, 2010; Harris, 2012) as well as others (e.g., Robinson et al., 2011). In the research by Harris and his colleagues, 4- and 5-year-old children are typically confronted with figures depicting hybrids of animals (i.e., they had features of two animals) and mothers or others named the animals. It has been found that young children select: (1) the name of the animal provided by their mothers when the object was a complete hybrid; (2) the accurate name of the animal when it had more distinguishing features (i.e., those distinctly of one animal) despite the mothers' selection of names; (3) the name of the animal provided by an adult's source with a history of accuracy rather than inaccuracy; (4) the name of the animal provided by others when expressed as a consensus, and (5) the name of the animal when the race of informants is the same as the child's (see Chen et al., 2013; Corriveau and Harris, 2010). These findings may be interpreted as showing that even very young children hold beliefs (and corresponding affect) regarding whether or not sources of communication are honest (i.e., truthful) and depend on those sources as a guide to their behavior.

The preceding line of investigation identifies the factors that affect children's reliance on others as a source of information and thus the children's acquisition of knowledge regarding science and religion (see Harris, 2012). These findings may be interpreted as showing young children engage in behavior-dependent trust as it pertains to honesty (Corriveau and Harris, 2010). This interpretation is uncertain because it is not clear that the children's behavior is a result of their sensitivity to the intentions of others (e.g., benign as opposed to malevolent) as required for honesty according to the BDT.

Children's Theory of Mind (ToM) comprises their ability to infer, and utilize in judgment, the premise that others have cognitive and emotional states such as intentions, desires, beliefs, knowledge, and emotion (see Peskin and Ardino, 2003). Research has demonstrated that young children's ToM is associated with their honesty trustworthiness, notably telling the truth rather than deceiving/lying (see Polak and Harris, 1999), and with their emotional trust beliefs (Rotenberg et al., in press).

Middle Childhood (7–12 Years)

During this period, parents continue to affect children's social cognition, affect, and behavior. The children become increasingly involved, however, in school, peer friendships, and peer groups (primarily same sex) and the neighborhood. As a consequence, children's honesty, reliability, and emotional trust both as beliefs and behavior are (1) affected by parents' trust beliefs and behavior (Rotenberg, 1995); (2) an integral part of same-sex peer friendships (Rotenberg, 1986); (3) part of peer-group interactions (Rotenberg and Boulton, 2013); (4) linked to their reasoning regarding social expectations and moral principles (Kahn and Turiel, 1988); (5) linked to the trustworthiness of their neighborhoods (Rotenberg et al., 2012); and (6) associated with academic achievement (Imber, 1973). Because of the increasing exchange of intimacies (secrets) between peer friends (see Rotenberg and Boulton, 2013), reciprocal patterns of emotional trust is shown during middle childhood.

Adolescence (13–19 Years)

Adolescents' sexual development, moral development, increased ability to comprehend abstract concepts, and their involvement in broader social networks and social events result in further changes in trust. As a consequence, adolescents' trust extends to sexual matters such as birth control and the contraction of sexually transmitted diseases including AIDS (see Lear, 1997). Also, adolescents begin to prepare for their role in democracy from their school involvement and to display concern with the moral issues pertaining to wider groups within society that bear on trust (see Flanagan and Stout, 2010; Settle et al., 2011). Adolescents' trust in institutions is lower than those found in older adults (Quintelier, 2007), and younger generations demonstrate lower generalized trust in others than do older generations (see Flanagan and Stout, 2010).

Early and Middle Adulthood (20–29 Years and 30–55 Years, Respectively)

During this period, individuals most commonly become involved in extended romantic relationships and enter the workplace. Accordingly, trust during this period is highlighted by trust within the context of romantic relationships. Trust in romantic partners is: (1) a defining aspect of their romantic attachment style notably security (Mikulincer, 1998), (2) undermined by reciprocal self-concealment (Uysal et al., 2012), and (3) linked to relationship-promoting memory biases regarding transgressions of partners (Luchies et al., 2013). Individuals' trust in marriage partners has been found to be associated with their love of their partners and the belief that partners are concerned about their (the individuals') welfare (Rempel et al., 1985). Also, there is evidence that individuals' show an impulsive form of trust, which increases their caring for their romantic partners (Murray et al., 2011). This period is also marked by trust issues concerning superiors and coworkers in the workplace, which affect psychosocial functioning and productivity (see Knoll and Gill, 2011). All bases, domains, targets, and

dimensions of trust in Rotenberg's (1994) framework are viable throughout adulthood.

Later Adulthood (55–75 Years)

This period is marked by individuals' concerns over quality of life and physical safety. Older adults' trust centers on the extent to which their offspring (adult children), social networks, and social agencies will provide care and help to establish or sustain a satisfactory quality of life (Bierhoff, 1992). Weak trust beliefs in family and friends or neighbors are associated with a subjective sense of insecurity during this age period (Fagerström et al., 2011). During this period, individuals are concerned about their vulnerability to being victims of crime and thus their trust centers on their physical safety (Rotenberg, 1990).

Very Old Age (75+ Years)

During very old age, individuals confront issues of distribution of inheritance and, as a consequence, reevaluate their trust in family members. They deal with the issue of their immortality and specifically whether the trust they place in family members and perhaps in society or mankind to construct a better world will be confirmed after death. It is important to note that research shows that the holding low generalized trust in others by individuals is predictive of their mortality, notably in males (Barefoot et al., 1998; Nummela et al., 2012). Among other interpretations, this longitudinal relation may be attributed to trust beliefs serving as a buffer to stress or to distrust per se as a stressor that reduces health and, in turn, results in mortality.

Psychosocial 'Consequences' of Childhood Trust

Erikson (1963) proposed that trust versus mistrust was the first of the eight stages of psychosocial development and evidenced during infancy. The resolution of that stage was believed to affect the healthy to unhealthy psychosocial resolution of subsequent stages during the course of development. Although there is dearth of research directly examines that hypothesis, researchers have investigated whether or not later psychosocial functioning across the life span is a consequence of childhood trust. Malti et al. (2013) carried out a four-wave longitudinal investigation of 1028 children that ranged from 8 to 11 years of age. Latent growth-curve analyses demonstrated that low trustworthiness (i.e., low promise-keeping behavior) was predictive of stable aggressive behavior as reported by teachers. In a related study, Rotenberg et al. (2004) examined trustworthiness, as assessed by peer-reported promise-keeping and secret-keeping, and the number of friendships for children/early adolescents from Canada and the United Kingdom. It was found that trustworthiness longitudinally predicted the number of friendships across an 8-month or 1-year period.

As further investigation of the potential consequences of childhood trust, Qualter et al. (2013) examined the relation between trust shown by 7-year-olds and their psychosocial and health functioning at 2-year intervals until they were 17 years of age. Qualter et al. (2013) found that children's reliability-based trust beliefs in others and behavior-dependent trust on others longitudinally predicted stable low loneliness across time. In a related study, Rotenberg et al. (2010) carried a short-term longitudinal examination of the relations between trust beliefs (reliability and emotional) during early childhood, middle childhood, and early adulthood. It was found that trust beliefs longitudinally predicted low loneliness in each age group. The findings show that psychosocial functioning such as low loneliness and low aggression is a probable consequence of children's trust beliefs and trustworthiness. It should be emphasized that the findings suggest that those are probable consequences because they represent associations across time, albeit longitudinal in nature. Also, the research has not yet addressed whether those consequences persist across the entire life span.

Are Children with Very High Trust Beliefs at Risk for Psychosocial Problems?

There is a growing body of research showing that children with very high trust beliefs are at a risk for psychosocial problems. Rotenberg et al. (2005) found curvilinear U-shape (quadratic) relations between 9- and 11-year-old children's trust beliefs in the peer group/peer friends and psychosocial functioning. Children with very high and those with very low trust beliefs were more rejected by peers, more excluded by peers, and held lower perceptions of self-perceived social acceptance, than were children with midrange trust beliefs. Children's trust beliefs linearly predicted changes in psychological maladjustment (depression, loneliness, and anxiety) but that was qualified by a quadratic pattern. Children with very high and those with very low trust beliefs showed elevated levels of changes in psychological maladjustment compared to a linear relation. Also, quadratic relations showed that, compared to children within the middle range of trust beliefs, children with very high trust beliefs and those with very low trust beliefs in peers were (1) lower in self-perceived social acceptance, (2) more excluded by peers, and (3) more rejected as opposed to accepted by peers. Similarly Betts et al. (2009) found quadratic patterns in 5- to 7-year-old children. Children with very low and those with very high generalized trust beliefs in other and demonstrated greater loneliness and fewer friendships than did children with the middle range of generalized trust beliefs. The findings attest to the principle that being 'too trusting' can have detrimental effects. Research has not yet shown that that pattern is evidence during other periods in development.

Summary

The proposed developmental pattern redresses the lack of such a proposal in the field. It is hoped that the currently proposed pattern, when linked to research, will both shed light on individuals' experience of trust during the life span and promote relevant research. Although, the growth of research on trust is unprecedented, the body of knowledge is not growing accordingly because of the diversity of conceptualizations and measures of that construct. The BDT framework and the proposed developmental offers hope for integrating the expanding work on the topic of trust.

Interpretation in Anthropology

Johannes Fabian, University of Amsterdam, Amsterdam, The Netherlands

This article is reproduced from the previous edition, volume 11, pp. 7874–7878, © 2001, Elsevier Ltd.

Abstract

Interpretation, often paired with or opposed to explanation, signifies practices (including methods of selecting and preparing ethnographic material, ways of defining questions and arguing positions, and styles of writing) by which anthropologists produce and represent knowledge. The idea goes back to a tradition of text-oriented critical philology and history that, together with the project of a natural history of mankind, emerged as the discipline of anthropology during the Age of Enlightenment. Approaches to interpretation in anthropology that were developed subsequently varied depending on how the discipline defined its object of study (for instance, as a historical record, as the result of processes of evolution, or as symbol-based systems orienting action). Throughout this period, interpretation retained its general meaning, until in the 1970s, pleas for an interpretive or hermeneutic anthropology were formulated by those who argued that cultural anthropology could not be practiced either as a (narrowly defined) natural science or as a purely semiotic discipline. Assigning central importance to the concept of text (and context) was a common feature of this critical movement; its strategies varied greatly between promoting text as a metaphor for culture, regarding ethnographic data as texts, promoting performative views of culture as texts-in-action, and calling for attention to the political aspects of investing texts with authority.

Since the beginnings of the discipline, interpretation has occupied and affected everyone who practices anthropology. Being all-pervasive, a concept or practice can become invisible such that in most standard works on the theory and history of anthropology 'interpretation' does not rate an entry in the index, and that goes, curiously, also for the book that more than others put interpretation on the map of debates in recent anthropology (Geertz, 1973). Half a decade later, anthropology figured prominently among the social sciences that were said to have turned to an 'interpretive or hermeneutic approach' (Rabinow and Sullivan, 1979, but see Bauman, 1978 for the long and deep history of the challenge of hermeneutics). Significantly, this claim was made in a Reader, a collection of authoritative essays. As a genre of scholarly books, we expect Readers to appear when a theoretical concept and its attendant practices of research and writing are either programmatically announced or have already congealed as a distinctive (sub)discipline. The latter, as far as we can tell, has not happened. Since a clearly defined hermeneutic anthropology does not exist, a statement about 'interpretation in anthropology' is a peculiar task, and one which calls for narrative rather than systematic presentation.

The Burden of History: Hermeneutics

A way to get a grip on elusive 'interpretation' in anthropology is to trace the concept to the discipline's modern beginnings. Most historians locate them in the Age of Enlightenment, and this proves helpful provided that the scope is not narrowed unduly (and anachronistically) to a search for eighteenth-century predecessors of anthropology as a natural or social science. Thinkers whom we recognize as proto-anthropologists formulated their ideas in a context of theological, philosophical, and (often overlooked) philological debates. These debates were carried out in a field of tension that developed between the Enlightenment and, largely contemporary, Romantic thought (a complex story still best covered in Gusdorf, 1973). From this broader view of our genealogy one can derive a heuristic model whereby modern conceptions of interpretation are seen to go back to moves between two poles. One of them is a long tradition of the exegesis of authoritative texts such as the Scriptures, the Classics but also corpora of Law. Typically, interpreters of such texts partook in the authority of their sources and had an interest in promoting and defending a transhistorical status for their sources. At the other pole, we find a tradition of secular critique. It emerged from moves to historicize authoritative texts by submitting them, often building on methods and techniques developed by theological and philological exegetes, to literary, social, and political analysis and interpretation (a conceptual pair that shows up also in most modern writings). Biblical criticism and what was called the Homeric question had demonstrated that these texts of quasi-transcendent religious and aesthetic authority had a mundane history of creation, collection, and editing under multiple individual and collective authorship. Because they had a past they were relevant to a critical understanding of the present. In a line leading from Hegel to Marx and Weber, to reveal the historicity of human affairs became a foremost task of social science.

Anthropology owes its openness to ideals of rational inquiry into, and appreciation of, the creations of other traditions ('cultures') at least as much to this secular tradition of critical interpretation as to the principles and habits of natural science. Given this double inheritance, distinctions between interpretive hermeneutic and explanatory scientific positions that keep the two facing each other in binary opposition become stultifying. The same applies when exegesis, interpretation working close to the material surface of texts, is contrasted with hermeneutics concerned with deep meanings. Least of all do such divisions correspond to that between a subjective quest for authority and power and the objective pursuit of scientific truth. Those who interpret and those who explain have about the same potential for turning into authoritative pundits. In sum, to acknowledge the double genealogy of anthropology in a hermeneutic and a scientific

lineage maps a conceptual space necessary to discuss interpretation in anthropology; distinctions between them do not validate or invalidate, or even classify approaches.

While unproductive oppositions should be rejected, it is important to keep in mind that, in its modern usage, interpretation has been a critical and often militant concept. To cite one of Bauman's conclusions: "*The method of sociological hermeneutics,* like that of empirical science, *can serve the practice of communication only in its negative capacity, as the method of criticism*" (1978: p. 241, emphasis in the original).

Interpretation and the Object of Anthropology

Anthropology may have owed much to a tradition of critical interpretation, and J. G. Herder, a thinker steeped in that tradition, can be credited with having bequeathed to anthropology essential elements that went into its guiding idea, culture. Yet interpretation or hermeneutics did not assume a prominent position in debates about the production of anthropological knowledge until the late 1960s. Of the two paradigms under which anthropology gained admission as an academic discipline toward the end of the nineteenth century, evolutionism (as represented by E. B. Tylor) emerged from the Scottish Enlightenment and embraced principles and taxonomic methods of natural history. It derived its methods above all from disciplines such as geology, biology, and comparative anatomy. Diffusionism can be traced to the Romantic project of a universal cultural history but it practiced a hermeneutic that had been narrowed to a positivist methodology of interpreting historical sources, as exemplified in F. Graebner's (1911) adaptation of the work of E. Bernheim (1970, orig. 1889), a medieval historian. In both paradigms, notwithstanding the literary ambitions of some proponents, such as James Frazer, and the influence of literary critic Matthew Arnold on E. B. Tylor, anthropology seemed to lack an object for critical interpretation comparable to the great texts, the Scriptures, or the Classics. This did not change with the succeeding paradigms of British functionalism, French structuralism, or even (and at first) American culturalism. Primitive, nonwestern societies were not to be interpreted; they called for functional explanation, structural decoding, or structural-functional systemic analysis, until the study of cultural 'meaning' took the center stage.

This last development was tied to the concept of symbol that, unbeknownst to many who wielded it (leaning on Freud, Cassirer, Kenneth Burke, or Susanne Langer), always threatened to take anthropology back to precritical hermetic traditions of interpretation. Most daringly stated by Roy Wagner (1975), a 'symbolic anthropology' staked its claims – also with a Reader (Dolgin et al., 1977) – at about the time when calls for an 'interpretive and hermeneutic' approach were first heard (possibly prepared by Palmer's excellent general introduction to hermeneutics in English published in 1969). Clifford Geertz was invoked as an authority by the symbolic as well as the interpretive movement. He remained somewhat aloof of both and continued to call his approach semiotic (i.e., sign-centered) although he went further in the direction of hermeneutics than any of his predecessors when he suggested that anthropology's object of study, culture, might be approached as (or like) a text (an 'ensemble of texts' in his words). Geertz referred to an essay by Paul Ricoeur (1971, reprinted in Rabinow and Sullivan, 1979: pp. 73–101). Ricoeur had advanced the 'hypothesis' that the human sciences, by adopting a hermeneutic approach, could proceed from 'Explanation to Understanding' (for a broader statement of the relevance of hermeneutics and interpretation to the social sciences, see Ricoeur's influential study of Freud, 1970). Earlier influences from Dilthey and Weber had prepared the ground for giving to 'understanding' this new and sharp focus.

Interpretation and Method

Thus, by the mid-1970s, one of its most influential proponents seemed to have steered anthropology back to the Romantic tradition of interpretation. However, important as this move may have been at the level of theory (i.e., in redefining the object of anthropology and in clarifying the status of the discipline as an interpretive rather than explanatory science), its practical consequences were limited. The model of the text did not generate a new distinctive method; thick description and a knack for discerning 'webs of signification' continued to work as the ethnographer's 'magic.' For those who embraced the hermeneutic stance, text remained essentially a metaphor and few among these writers were compelled by this figure to direct their ethnographic research and writing to actual texts and their interpretation. The latter happened in a movement that was roughly contemporary with Geertzian hermeneutics and had intellectual roots that, acknowledged or not, go back to W. von Humboldt. It took its departure from a critique of formalist structural linguistics, of purely classificatory approaches in folklore, and of positivist views of ethnography. It was in this field of innovative endeavors where critical thought in language-centered anthropology (Hymes, 1974) and the philosophy of social science (Habermas, 1988, orig. 1967) converged that we began to see how interpretation might develop from a theoretical figure to a practical guideline, a method organizing the production of anthropological knowledge from field research to writing.

Whether or not certain choices, steps, procedures, and strategies devised for interpretation can count as an anthropological method is an epistemological question: how must we conceive the nature of anthropological inquiry, how the nature of its object? From a hermeneutic position the answer would roughly be this: anthropology, though aware of, and in some of its branches concerned with, neural, etiological, and certain statistically demonstrable determinations of human behavior, starts with the assumption that human experience as well as the study of that experience are always mediated. Mediated means that experiences (and our understandings) are made, shared, and transmitted by means (lit. things in the middle, media) that include language (in the broadest sense of the term), practices of communication and representation, and material objects. This is an epistemological, not an ontological view: When we conceive of an ensemble of mediations as culture this is not to posit culture as an entity. Culture is a discourse on mediations and practices. In this view, mediations are objectifications of human action somewhat but (as we shall argue) not quite in the sense envisioned by Ricoeur when he stated

that "action itself, action as meaningful, may become an object of science, without losing its character of meaningfulness, through a kind of objectification similar to the fixation which occurs in writing. By this objectification action … constitutes a delineated pattern which has to be interpreted according to its inner connections" (1971: p. 538). The analogy with fixation in writing (the reason to introduce the model of the text in the first place) "prepares the detachment of the *meaning* of the action from the *event* of the action" (1971: p. 538). In the passages from which these quotations are drawn Ricoeur deploys the vocabulary of Weberian–Parsonian culturalism (pattern, meaning, meaningful action, interaction) and thereby advocates interpretation as an operation on elements of culture that, though objectified, are disembodied – a point often made in the critique of American culturalism and echoed in Bourdieu's (1977: p. 96) qualifying the hermeneutic stance as 'objectivism.'

In contrast, approaches to text and interpretation in anthropology that, explicitly or not, focus on mediation and on culture as praxis are concerned with maintaining or restoring the event-character of action. Interpretation then becomes a method of translating the texts and documents, that is, those 'fixations in writing' that are the 'data' produced by interactive, communicative ethnography (notes, recordings, collected texts, including some that made their way into historical or administrative archives), into events and eventually into processes. Not the model of 'the' text but models of text making are required for such interpretive work, much of which has been inspired by Dell Hymes's (1974: orig. 1964) seminal observations on components of speech events. His ideas, sometimes called 'sociolinguistic,' were further developed by the contributors to Bauman and Sherzer (1974). Linking the notion of speech event to that of genre, Dan Ben Amos has shown methodological consequences for folklore studies (1976), and a classic in this vein is Dennis Tedlock's collection of essays (1983). Fabian has stated the philosophical (anti-positivist) point of departure, offered a model of text production, and a warning against tendencies to grammaticalize Hymes's pragmatic approach to texts (1991, Chaps. 1, 3, 5).

Interpretation and Performance

The move away from semiological to pragmatic concerns reflected and promoted yet another understanding of interpretation. 'Interpretation' used to be a discipline and skill taught in speech and drama departments; today, many of them have become part of a multifaceted field called Performance Studies. Performance, as a theoretical concept usually paired with 'competence,' was adopted by Hymes from generative linguistics and applied to his ethnography of speaking but it undoubtedly gained its wider currency in anthropology in the more specific, theatrical understanding promoted, above all, by Victor Turner (stated most comprehensively in 1986). Actually, as his work shows, attention to performance in the interpretation of culture has a complex intellectual history. Turner began by giving focus and life to drama, a pervasive but mostly dead theatrical metaphor in social theory (for instance, in Parsonian functionalism–structuralism) that was at the origin of such crucial sociological terms as role, actor, and enactment. He saw drama above all in ritual, and came close (as did Max Gluckman) to postulating a distinctive type of premodern society whose social dynamic was not determined by linear accumulation of change and innovation but by cyclical enactment of a dramatic script. Undoubtedly, this presented a gain over static views of primitive or traditional societies. However, not unlike the model of culture as a text, the drama metaphor had its limits when it came to understand its practical consequences for the production of ethnographic knowledge. What was needed was an epistemological conception of performance as both a way in which a culture works and a method by which it may be studied and represented. Taking an increasingly literal approach to performance as theatrical performance (including experimental collaboration with Richard Schechner, a producer and theorist in the field of theater), Turner ended in an impasse that eventually led him to advocate a biological (neurological) position not unlike that earlier taken by Lévi-Strauss (see Turner, 1986: pp. 156–177). Nevertheless, his work helped to make anthropologists aware that large parts, perhaps most expressions, of cultural knowledge are performative in the sense that what they say is also constituted by how contents are enacted. An emerging 'ethnography of reading' (Boyarin, 1993) applies this to texts fixated in writing and opens to anthropology a wide field of interpretation no longer predicated on categorical distinctions between orality and literacy; for methodological consequences and procedures, see Finnegan (1992) and Tonkin (1992). What changed, and was gained, by including pragmatic (sociolinguistic) and performance aspects in methods of interpreting oral sources is best illustrated by comparing Vansina's classic work on oral tradition (1961) with its radical revision (1985).

Finally, it should be mentioned that a pragmatic and critical stance toward the interpretation of texts also leads to a re-evaluation of 'context,' a concept that has had a long history in anthropology. It was applied mainly in the validation of ethnography and often, much like text, in a metaphorical manner in admonitions to place specific facts or data in their historical, political, economic, religious, etc. 'context.' In-as-much as this suggested that, though relevant to an interpretation of findings, context was itself not subject to interpretation (at least not at the moment when it was invoked), this has become an untenable proposition. Context poses problems of interpretation, it does not solve them.

The Politics of Interpretation

A review of theoretical and practical views of interpretation in anthropology would not be complete without developments that emerged in the 1980s. They consisted of moves giving anthropology a 'literary turn,' an apt designation if it is understood as promoting attention to writing in the production of ethnography and anthropological knowledge. Not metaphorical invocations of text as a model, but calls for critical interpretation of ethnographies as texts were formulated by a group resolved to lift the veil under which modern, scientifically minded anthropology had kept ethnographic authorship (Marcus and Cushman, 1982, Clifford and Marcus, 1986, Clifford, 1988). Postmodernism became a convenient but doubtful label for this movement – doubtful because it obscures

its roots in decidedly modern advancements in the historiography of our discipline, in the theoretical confrontation with its colonial and postcolonial political role that had occupied critical anthropology since the 1960s, and, though less obviously, in feminist critique of anthropological discourse.

As regards interpretation, the subtitle of the Clifford and Marcus volume, 'The Poetics and Politics of Ethnography,' pointed to the directions further work could, and did, take. Along the lines of a hermeneutical understanding of the term, interpretation now applied to the canon of anthropological writing the tools developed by literary theory and criticism (exemplified by Geertz, 1988). Interpretation in the performative sense encouraged, beyond literary deconstruction, 'experimentation with genre' which resulted, if not quite in its demise, then in relativizing the status of the monograph as the authorized form of ethnography: narrative, dialogue, poetry, collage, and autobiographic inclusion of the ethnographer in his or her account have begun to shape much of anthropological writing. Perhaps it is not always easy to draw a line between hard-won freedom from scientism and gratuitous literary posing; postmodern ethnography is at its best when it is able to justify its choice of representational forms on epistemological grounds.

How an author translates practices of research into writing has become a foremost task of critical interpretation in anthropology. To be able to discern narrative plots and strategies, identify tropes and other rhetorical devices, and to recognize intertextual connections is now required when we discuss the validity of ethnographies. Conversely, though it would be foolish to cast away all our prior habits and techniques, field research can no longer rely largely on preconceived methods that once were thought to yield data without being themselves subject to constant interpretation (which would have made methods useless in a classical positivist research setup). Attempts to formulate these insights have reached the level of textbooks and handbooks that steer a difficult course between opening a back door to flat-footed methodology and scaring anthropological novices with hermeneutic hypersensitivity.

Distinguishable but never separable from attention to poetics is the concern with the politics of ethnography, that is, with relations of power that determine production of anthropological knowledge in all its phases from research to writing. Therefore the question of interpretation in anthropology cannot be raised without (taking a lesson from Michel Foucault) questioning the devices of control and domination deployed in the discourse anthropology pronounces on others. Interpretation may be 'just interpretation,' but neither as a hermeneutic alternative to scientism nor as a pragmatic method should it make anthropology complacent about its achievements.

Interpretive Methods: Macromethods

Abstract

This article uses Weber's work to elucidate key features of macrointerpretive methods. Although relying on a logic different from that of frequentist statistical methods, macrointerpretive methods are based on coherent methodological principles and procedures. The goal of all macrointerpretive method is to render large-scale social actions and processes intelligible. Imputation of chains of meaning, motivation, and consequent likely courses of action are one hallmark. Macrointerpretive work is profoundly historical, and is well suited to reconciling agency and structure. It exhibits a continuous interplay of ideas and evidence, and combines inductive with deductive reasoning to solve anomalies, explain historically specific event sequences, and seek limited historical generalizations that are value-relevant and culturally significant. Enriched by multiple analytic techniques including diverse formal and nonformal narrative and comparative methods, macrointerpretive scholarship embodies tensions between the prominence accorded to narrative vs. comparisons, the concrete and particular vs. the abstract and general, conceptual understanding vs. causal analysis, and subjectivism vs. objectivism. Although built around a diversity of techniques, macrointerpretive scholarship of all sorts is well suited to forming and empirically examining concepts, hypotheses, and theories that help us understand how social structures work, how they reproduce themselves, and how they change.

The goal of all interpretive methods, both macro and micro, is to make sense of some slice of reality – to render it understandable or intelligible. Since the work of Max Weber (1949, 1958, 1978) has been central to articulating macro interpretive methods, this essay uses Weber's work to elucidate key features of these methods and to help outline their key tensions.

Weber's Protestant Ethic *as an Illustrative Case*

Weber's (1958) *The Protestant Ethic* exemplifies the meaning-oriented (verstehende) and explanatory goals and strategies of macrointerpretive work. Noting a historical association between the Protestant reformation and the rise of capitalism in Western Europe, Weber outlines a puzzle. How could a religion leading to more *conformist* behavior than did Catholicism become associated with radically *innovative* economic behavior? Unraveling this historical and theoretical puzzle requires understanding the cultural beliefs occasioned by the Reformation and the dilemmas they created for the Protestant believer. Detailing exactly how the new beliefs provided for social control allows Weber to make sense of a culturally significant and historically specific pattern of institutional change.

To do this, Weber constructs the ideal types 'capitalist ethos' and 'Protestant ethic.' *Ideal types* are analytic tools for interpretive, explanatory work. The social scientist creates ideal types by abstracting elements from concrete historical situations, then combining the elements into a meaningful conceptual whole. The ideal type does not exist in empirical reality, but it is constructed inductively from that reality to illuminate something of cultural significance (Weber, 1958, p. 47,1949, pp. 91–111,1978, pp. 18–22).

According to Weber (1958: 51–68), the spirit of capitalism combines two elements: an absolute ethical duty to accumulate capital and to do so in a rigorously calculating rational way. The ideal-typical capitalist must increase his or her capital as an end in itself, methodically identifying and following courses of action that lead to profit-making, while strictly avoiding any enjoyment of life. Weber argues that any account of the rise of modern capitalism must explain how this ethos, which then helped transform economic institutions, evolved.

The ideal-type Protestant ethic analytically combines three elements (Weber, 1958: 79–154). First is Luther's idea of the calling – that people have a moral duty to their work. Second is ascetic mastery of the world, the idea that at each minute of every day, the individual must bring God's glory to fruition in the world, rather than by withdrawing to a monastery or nunnery. Third is the Calvinist doctrine of predestination, arguing that by the decree of God for the manifestation of God's glory, some people are predestined for grace and others for damnation. Only God knows which people are which, and nothing people do in their lives can change their preordained fate.

Once Weber has theoretically constructed his object of inquiry – the capitalist ethos – and his explanatory concept – the Protestant ethic – he creates the interpretive links tying the two together. He asks and answers the question, what does predestination *mean* and how is it likely to orient behavior for the people who believe in it, given that they *also* believe in the calling and ascetic mastery of the world? He then argues as follows.

> In its extreme inhumanity, this doctrine must above all have had one consequence for the life of a generation [that] surrendered to its magnificent consistency. This was a feeling of unprecedented inner loneliness of the single individual. In what was for man of the age of the Reformation the most important thing in life, his eternal salvation, he was forced to follow his path alone to meet a destiny which had been decreed for him from eternity … the complete elimination of salvation through the Church and the sacraments was what formed the absolutely decisive difference from Catholicism.
>
> (Weber, 1958: 104)

Attaining salvation is so central that believers will question constantly whether they are saved. Since there is no way of

knowing, most people will feel intolerable psychological strain. Strain is amplified because at the same time that participation in Protestant churches and rituals cannot guarantee salvation, believers are told by religious leaders that it is "an absolute duty to consider oneself chosen … lack of self confidence is the result of insufficient faith, hence of imperfect grace" (Weber, 1958: 111). It becomes imperative to resolve this 'Catch-22' situation and justify certainty in one's salvation.

What will the believer do? Faced with a preordained outcome, some people might become fatalistic and others might commit suicide. To explain why believers do not take these paths, Weber situates predestination in its broader belief context. Because of the conjunction of belief in predestination with beliefs in the calling and ascetic mastery of the world, the Protestant believer is likely to try and relieve his or her incredible psychological insecurity by bringing God's glory to fruition through efficacious action in a calling in the world. 'Good works' cannot bring salvation, but they *do* provide an effective way to get rid of the fear of damnation, assuming that the believer lives an entire "life of good works combined into a unified system" (Weber, 1958: 115–117).

In short, predestination and the need for proof of salvation provide a psychological basis for constant self-regulation and the rational ordering of moral life. The other elements of the Protestant ethic explain how and why the solution to the need for proof will be found in the systematic rationalization of moral life in the world rather than being found elsewhere. As a meaningfully interpreted whole, the Protestant ethic is powerful brew. The interpretive link to the capitalist spirit now is clear: purposive-rational orientation to capital accumulation as an end in itself is a strategy to provide the believer with a clear, continuous and unambiguous sign of his or her own salvation. As a collective attribution of meaning and action orientation, the strategy – and the macro religious structure that created it – unintentionally reorders economic behavior and institutions.

Key Features and Tensions in Macrointerpretive Work

As illustrated by Weber, imputation of chains of meaning, motivation, and consequent likely courses of action are a hallmark of macrointerpretive explanation. Because actors are front and center, with social institutions providing the cultural scripts that orient actors' attributions of meaning and their behavior, macrointerpretive work is ideally suited to reconciling agency and structure (Sewell, 1996). Similarly, macrointerpretive work is profoundly historical, although it is not necessarily historicist in the narrowest meaning of that term.

Because most macrointerpretive work is concerned with imputing actors' meanings, culture and ideology loom large as objects of inquiry or as explanatory factors (Wuthnow, 1989; Mahoney, 1999). However, macrointerpretive methods also signal the interrelated construction of historical narratives and social science concepts to interpret historical wholes, processes or particularities, so that they are rendered meaningful to us as social scientists (Ragin, 1987). These two analytically distinct aspects of macrointerpretive work tend to be found together, as in Weber's *Protestant Ethic*, but they sometimes appear separately (Mahoney, 1999).

Macrointerpretive scholarship is enriched by multiple analytic techniques including diverse formal and nonformal narrative and comparative methods (see, e.g., Ragin, 1987, 2000; Griffin, 1993; Stryker, 1996; Mahoney, 1999). Some scholars view strategies such as narratives stressing sequence, path dependence, and 'eventful temporality' and comparisons emphasizing the divergent structural and cultural contexts of events as alternative approaches to doing macrointerpretive work (Griffin, 1992; Sewell, 1996). However, others argue these strategies are complementary (Quadagno and Knapp, 1992; Stryker, 1996; Mahoney, 1999).

Like Weber's own work, macrointerpretive scholarship embodies a tension between the concrete and particular and the abstract and general (compare Bendix, (1978) with Moore, (1966)). Often, macrointerpretivists resolve the tension between specificity and generality, as did Weber, by using the concepts they create to resolve puzzles and explain historically specific events and event sequences, while also seeking limited historical, or conditional, generalizations (Quadagno and Knapp, 1992; Stryker, 1996; Mahoney, 1999; Paige, 1999). The underlying assumption about the relationship between history and social science theory guiding macrointerpretive work is that history is theorized at the same time as theory is historicized. In other words, the two are 'mutually constructed' and 'mutually adjusted' so that they are 'logically interdependent processes' rather than 'analytically independent things' (Stryker, 1996: 312).

Macrointerpretive work often is portrayed as wholly inductive. But as Weber's *Protestant Ethic* demonstrates, it cannot be characterized fairly in this way. Neither can its practitioners be characterized as formalistically applying Mill's method of agreement, indirect method of difference or some combination of the two. Notwithstanding much literature describing comparative variants of macrointerpretive methods in terms of Mill's canons, Goldstone (1997: 108) shows why 'Mill's methods cannot be used and are not used by comparative case-study analysis.' Instead, Goldstone, (1997) likens case-oriented comparative methods to sophisticated detective work. Like all macrointerpretive analysis, these methods involve a constant interplay of ideas and evidence to solve anomalies, they carefully combine inductive with deductive reasoning, and they involve attending to the complexities of multiple and conjunctural causation (Stryker, 1996; Goldstone, 1997; Ragin, 1987). A final hallmark of macrointerpretive scholarship is selection of research topics according to their 'value-relevance' and 'cultural significance' for the scholar and intended audience (Weber, 1949: 76–77; Sewell, 1996; Mahoney, 1999).

This run-down of multiple currents and tensions within macrointerpretive work is not exhaustive, but it should suffice to show that macrointerpretivists debate (a) whether or not interpretation must involve causal explanation as well as imputing meaning and (b) the prominence that should be accorded to narrative as opposed to comparative techniques. Much, but not all, macrointerpretive work is explicitly or implicitly causal-analytic (Skocpol and Somers, 1980; Ragin, 1987; Goldstone, 1997). Similarly, much macrointerpretive work is explicitly or implicitly comparative, even as it relies heavily on narrative strategies (Skocpol and Somers, 1980; Mahoney, 1999). For a good introduction to diverse causal-analytic strategies and to the multiplicity of comparative

techniques employed by macrointerpretivists, see Skocpol and Somers (1980), Skocpol (1984), Ragin (1987), Rueschemeyer et al. (1992), Goldstone (1997), and Mahoney (1999). For a good introduction to the diversity of narrative techniques, including very different concepts of narrativity and its role in macrointerpretive social science, see Stone (1979), Griffin (1993), Sewell (1996), Stryker (1996), and Somers (1997).

A final tension involves questions of subjectivity and objectivity in social science. Some contemporary scholars – notably feminist standpoint theorists such as Smith (1990) and Collins (1990) – suggest that it is neither possible nor desirable to transcend the lived experience of the actors one studies. Meanings should be imputed through dialogic techniques practiced with real subjects or, if this is not possible, with historical texts, so that the actors studied would recognize and verify these meanings as their own.

Deconstructionist critiques such as these have been useful to elucidate how class, race, gender, and other categories of domination and subordination are implicated in the production of social science knowledge. However, most macrointerpretive scholars follow Weber (1949) in assuming that *interpretive objectivity* is both possible and desirable. Although there is substantial disagreement over which concepts and procedures are best, most macrointerpretive scholars presume that if the analyst is clear about his or her concepts and how they are operationalized and if he or she employs an explicit set of procedures to establish the interpretations he or she makes, he or she can arrive at interpretive objectivity. Here Weber's (1949, 1978) discussion of the use of ideal types, counterfactuals, and principles of objective possibility to arrive at explanations that are causally adequate and adequate on the level of meaning is seminal. Contemporary promotion of techniques of 'strategic narrative,' (Stryker, 1996), of formal qualitative comparative analysis and its extension into fuzzy set logic (Ragin, 1987, 2000), and of event structure analysis (Griffin, 1993), can be seen as updates on Weber's (1949) rules for achieving objectivity in macrointerpretive social science. In these extensions, issues of validity, reliability, and replicability are emphasized.

Conclusion

In sum, there is no one macrointerpretive method. Macrointerpretive scholarship is built around a diversity of techniques. Both old methodological stalwarts and new developments are playing their role in generating the culturally significant findings of macrointerpretive research. In the twenty-first century, there is an enormous body of writing illuminating the rich variety found within macrointerpretive methods. What all varieties share with Weber's *Protestant Ethic* is an emphasis on imputing meaning to render largescale social actions and processes intelligible. As comparisons of such diverse studies as Wallerstein's (1974) on the world system and Somers (1997) on English working-class formation suggest, macrointerpretive scholarship of all sorts is well suited to forming and empirically examining concepts, hypotheses, and theories that help us understand how social structures work, how they reproduce themselves and how they change. Although macrointerpretive scholarship relies on analytic logic completely different from that of frequentist statistical methods, it proceeds based on coherent methodological principles and procedures.

This article is reproduced from the previous edition, volume 11, pp. 7881–7885, © 2001, Elsevier Ltd.

Abstract

Recent developments in qualitative research are analyzed. Qualitative inquiry is located within an interdisciplinary and historical framework. The uses and forms of qualitative inquiry are reviewed, including those forms associated with participative, action research. Speculations on the future of interpretive, mirco-methods are offered.

In this article, recent developments in the uses and representations of interpretive, research methods are analyzed. Micromethods are focused on those interpretive approaches which yield close readings of texts and social situations. This will require serious attention to forms of narrative analysis, and the uses to which narrative material can be put by a society and its members, including social scientists. Accordingly, my intentions are fourfold. First, to analyze the problems and issues confronting the use of micro-qualitative methods and research evidence. Second, to define and locate this sprawling, interdisciplinary field of qualitative inquiry within the history of interpretive methods in the United States in the twentieth century. Third, to discuss the multiple uses and forms of qualitative inquiry, including its uses in participatory, applied action research settings. Speculations on where interpretive narrative inquiry will go in the twenty-first century form the conclusion.

The Field of Interpretive Research and its History

Interpretive research methods produce descriptions and accounts about the ways of life of the writer and those written about. There are multiple forms, or strategies of qualitative research (see below), including ethnography, participant observation, and case study analysis. The use of these strategies is connected to specific methodological practices, ranging from interviewing, to participant observation, to the use of visual, narrative, and personal experience methods. These methods generate specific types of empirical materials. These materials come in multiple forms, ranging from transcribed interviews and field observations, to life stories, cultural texts (stories, music, cinema, soap operas, TV news, televised sporting events), the artifacts and symbols of material culture (building and burial sites, pottery, tools, clothing), photographs, archival records, biographical, and historical documents. Traditionally, these materials are seen as producing the evidence that qualitative researchers use when they formulate interpretations of social and cultural phenomenon. Three interconnected activities define the interpretive research process. They go by a variety of labels or names, including theory, method, and analysis. Behind these terms stands the researcher who has a gendered biography, and who speaks from a particular class, race, cultural, and ethnic perspective. This researcher confronts the world with a set of ideas, or basic beliefs. These beliefs can be called a paradigm (Guba, 1990). A paradigm consists of an epistemology, an ontology, and a set of research strategies. Specific types of methodological practice are specified by a paradigm's epistemology. Ontology raises basic questions about reality and the nature of human nature. Methodology addresses the issue of how we gain knowledge about the world. Today in qualitative inquiry multiple paradigms, each with its particular ontology, epistemology, and methodology, compete for attention. These paradigms include logical postivism, postpositivism, constructionism and feminism, Marxism and critical theory, cultural studies and ethnic models. (Logical positivists believe in an external reality that can be apprehended by the methods of objective science. In contrast, postpositivists assert that there may be an external reality, but it cannot be known perfectly.)

The positivist paradigm, within interpretive methodology, presumes an objective world that can be studied with objective, micro-research methods. The constructivist paradigm presumes multiple realities, and contends that the researcher and those studied create understandings about the world and its meanings. Terms like trustworthiness, credibility, transferability, dependability, and confirmability replace the traditional positivist criteria of internal and external reliability and validity. Feminist, ethnic, critical theory, and cultural studies models privilege a real world that makes a material difference in the lives of men, women, and children. Interpretive methods are used, and researchers experiment with new ways of writing and presenting empirical evidence.

These paradigms, which structure qualitative research, operate in a complex historical field which cross-cuts five historical moments. These five moments simultaneously operate in the present. They are defined as the *traditional* (1900–50), the *modernist*, or golden age (1950–70), *blurred genres* (1970–86), the *crisis of representation* (1986–90) and *postmodern*, or present moments (1990–present). The present moment is defined by the refusal to privilege any method or theory, or methods claim to validity.

Successive waves of critical, epistemological discourse move across these five moments. The *traditional period* is associated with the logical positivist, quantitative research paradigm. In this period qualitative researchers attempted to justify their research methods in terms of traditional criteria of reliability and validity. Researchers sought to maintain a detached, objective stance toward the world and their objects of study. Research methods were the means by which evidence about the

world was collected. The other who was studied was alien, foreign, and strange.

The field worker, during this period, was lionized, made into a larger-than-life figure who went into and then returned from the field with stories about strange people. These accounts were structured by the norms of classical ethnography. This sacred bundle of terms (Rosaldo, 1989: p. 31) organized ethnographic texts in terms of four beliefs and commitments: a commitment to objectivism, a complicity with imperialism, a belief in monumentalism (the ethnography would create a museum-like picture of the culture studied), and a belief in timelessness (what was studied never changed). This model of the researcher, who could also write complex, dense theories about what was studied, holds to the present day.

The *modernist* and *blurred genres* moments are connected to the appearance of postpositivist arguments. The logic of multiple methods (and triangulation) was adopted, embodied in the development of empirically grounded theory. During this period, researchers started to move away from the detached observer stance of the traditional moment. At the same time a variety of new interpretive, qualitative perspectives made their presence felt, including hermeneutics, structuralism, semiotics, phenomenology, cultural studies, and feminism.

The modernist phase or second moment builds on the canonical works from the traditional period. Social realism, naturalism and slice-of-life ethnographies are still valued. This was the golden age of rigorous qualitative analysis.

By the beginning of the third stage (1970–86), *'Blurred Genres,'* qualitative researchers had a full complement of paradigms, methods, and strategies to employ in their research. Geertz's two books, *Interpretation of Cultures* (1973) and *Local Knowledge* (1983), defined the beginning and end of this moment. In these two works he argued that the old functional, positivist, behavioral, totalizing approaches to the human disciplines was giving way to a more pluralistic, interpretive, open-ended perspective. This new perspective took cultural representations and their meanings as its point of departure. Calling for 'thick descriptions' of particular events, rituals, and customs, Geertz suggested that all qualitative writings were interpretations of interpretations. The observer had no privileged voice in the interpretations that were written. The central task of theory was to make sense out of a local situation.

In the blurred genre phase the humanities became central resources for critical, interpretive theory, and the interpretive research project broadly conceived. The blurred genres phase produced the next stage, the crisis of representation. Here researchers struggled with how to locate themselves, their empirical materials, and their subjects in reflexive texts. It became increasingly clear that research methods were not neutral tools that produced value-free observations. Rather all observations were understood to be theory-laden; facts were not independent of the observer's values; and observers could not sustain an objective, detached view of themselves, the world, and the research process.

The *fifth moment* is the present. It is characterized by a sensibility which doubts all previous paradigms and historical moments. Theories are now read in narrative terms, as tales from the field (Geertz, 1988). Preoccupations with the representation of the 'Other' remain. New epistemologies from previously silenced groups emerge to offer solutions to this problem. The concept of the aloof researcher has been abandoned. Action, activist-oriented research is on the horizon, as are more social criticism and social critique. The search for grand narratives is being replaced by more local, small-scale theories fitted to specific problems and specific situations.

Reading History

The following conclusions can be drawn from this brief history. Each of the earlier historical moments continues to operate in the present, either as legacy, or as a set of practices that researchers follow or argue against. The multiple and fractured histories of qualitative research make it possible for any given researcher to attach a project to a canonical text from any of the previous historical moments. Multiple criteria of evaluation now compete for attention. There have never been so many paradigms, strategies of inquiry, or methods of analysis to draw upon and utilize. Researchers are in a moment of discovery and rediscovery, as new ways of looking, interpreting, arguing, and writing are debated and discussed. The qualitative research act can no longer be viewed from within a neutral or objective perspective. Class, race, gender, and ethnicity shape the process of inquiry, making research a multicultural process.

Interpretive Inquiry as a Site of Multiple Methodological Research Practices

Any definition of micro-interpretive research and the evidence generated by qualitative methods must work within this complex historical field. Qualitative research and qualitative evidence mean different things in each of these moments. Nonetheless, an initial, generic definition can be offered.

Interpretive inquiry is multimethod in focus, involving a naturalistic approach to its subject matter. This means interpretive researchers study things in their natural settings, attempting to make sense of these things in terms of the meanings people bring to them. *Qualitative research* involves the studied use and collection of case study, personal experience, introspective, life story, interview, observational, historical, interactional, and visual texts which describe routine and problematic moments and meanings in individual's lives.

Qualitative research, as a set of interpretive practices, privileges no single methodology over another. It has no theory, or paradigm that is distinctly its own. Multiple theoretical paradigms, as argued above, claim use of qualitative research methods and strategies, from constructivism, to cultural studies, feminism, Marxism, and ethnic models of study. Qualitative research does not belong to a single discipline.

These separate and multiple uses and meanings of the methods of qualitative research make it difficult to agree on any essential definition of the field, for it is never just one thing. Still a definition must be made. I borrow from, and paraphrase Nelson, Treichler, and Grossberg's attempt to define cultural studies (1992: p. 4).

> Qualitative research is an interdisciplinary, counter-disciplinary field. It cross-cuts the humanities, the social and the physical sciences. Qualitative research is many things at the same time. It is multi-paradigmatic in focus. Its practitioners are sensitive to the value of the multi-method approach. They are committed to the

naturalistic perspective; and to the interpretive understanding of human experience. At the same time the field is inherently political and shaped by multiple ethical and political positions. Qualitative research embraces two tensions at the same time. On the one hand it is drawn to a broad, interpretive, critical sensibility. On the other hand it is drawn to more narrowly defined positivist, postpositivist, humanistic and naturalistic conceptions of human experience and its analysis.

This rather awkward statement means that qualitative research, as a set of interpretive practices, embraces within its own history, constant tensions, and contradictions over the project itself, including its methods, and the forms its findings and interpretations take.

The Crisis of Interpretation

Today qualitative researchers confront a double crisis of representation and legitimation. Embedded in the discourses of poststructuralism and postmodernism (Denzin, 1997: p. 6; Lather, 1993), these two crises are, as Lather (1993) notes, coded in multiple terms, variously called and associated with the narrative, 'interpretive, linguistic, and rhetorical turns' in the social sciences. This linguistic turn makes problematic two key assumptions of social theory and interpretive research. The first assumption, as suggested above, presumes that theorists and researchers can no longer directly capture lived experience; such experience, it is argued, is created in the social text written by the researcher. This is the representational crisis. It confronts the inescapable problem of representation, but does so within a framework that makes the direct link between experience and text problematic.

The second assumption makes the traditional criteria for evaluating and interpretive theory and research problematic. This is the legitimation crisis. It involves a serious rethinking of such terms as validity, generalizability, and reliability, terms already re-theorized in postpositivist, constructionist-naturalistic, feminist, and interpretive discourses. This crisis, asks, 'How are interpretive, ethnographic studies to be evaluated in the poststructural moment?' Clearly these two crises blur together.

The Representational Crisis

A single but complex issue defines the representational crisis. It involves the assumption that much if not all social science and ethnographic writing is a narrative production, structured by a logic that separates writer, text, and subject matter. Any social text can, accordingly, be analyzed in terms of its treatment of four paired terms: (1) the 'real' and its representation in the text, (2) the text and the author, (3) lived experience and its textual representations, and (4) the subject and his or her intentional meanings. The text presumes a world out there (the real), that can be captured by a 'knowing' author through the careful transcription (and analysis) of field materials (interviews, notes, etc.). The author becomes the mirror to the world under analysis. This reflected world then re-presents the subject's experiences through a complex textual apparatus which typically mingles and mixes multiple versions of the subject. The subject is always a textual construction, for the 'real' flesh-blood person is always translated into either an analytic subject as a social type, or a textual subject who speaks from the author's pages.

Qualitative researchers have historically assumed that their methods probe and reveal lived experience. They have also assumed that the subject's word is always final, and that talk directly reflects subjective-lived experience. The literal translation of talk thus equals lived experience and its representation.

Poststructuralism challenges these assumptions. Language and speech do not mirror experience, they create it and in the process of creation constantly transform and defer that which is being described. The meanings of a subject's statements are, therefore, always in motion. There can never be a final, accurate representation of what was meant or said, only different textual representations of different experiences. As Lather (1993: p. 3) observes, these arguments do not put an end to representation, they signal instead the end of pure presence (Lather 1993: p. 3). The task at hand is to understand what textually constructed presence means, since there is only ever the text. This leads to the question of a text's authority.

The Legitimation Crisis

Many contemporary qualitative researchers challenge post-positivist arguments concerning the text and its validity. Lather (1993) and Scheurich (1997: p. 84) argue that validity is a text's call to authority and truth. Lather calls this version of validity epistemological. That is, a text's authority is established through recourse to a set of rules concerning knowledge, its production, and representation. These rules, as Scheurich (1997) notes, if properly followed, establish validity. Without validity there is no truth, and without truth there can be no trust in a text's claims to validity. With validity comes power, and validity becomes a boundary line 'which divides good research from bad, separates acceptable (to a particular research community) research from unacceptable research … it is the name for inclusion and exclusion' (Scheurich, 1997: p. 84).

Poststructuralism reads the discussions of logical, construct, internal, ethnographic and external validity, text-based data, triangulation, trustworthiness, credibility, grounding, naturalistic indicators, fit, coherence, comprehensiveness, plausibility, truth, relevance, as attempts to reauthorize a text's authority in the postpositivist moment. Such moves still hold (all constructionist disclaimers aside) to the conception of a 'world-out-there' that is truthfully and accurately captured by the researcher's methods and written text.

These words, and the methodological strategies that lie behind them, represent attempts to thicken and contextualize a work's grounding in the external empirical world. They represent efforts to develop a set of transcendent rules and procedures that lie outside any specific research project. These rules, if successfully followed, allow a text to bear witness to its own validity. Hence a text is valid if it is sufficiently grounded, triangulated, based on naturalistic indicators, carefully fitted to a theory (and its concepts), comprehensive in scope, credible in terms of member checks, logical, truthful in terms of its reflection of the phenomenon in question. The text's author then announces these validity claims to the reader. Such claims

now become the text's warrant to its own authoritative representation of the experience and social world under inspection.

Resistances to Qualitative Studies

The academic and disciplinary resistances to interpretive, micro-research further illustrate the politics embedded in this field of discourse. The challenges to qualitative research are many. Qualitative researchers are called journalists or soft scientists. Their work is termed unscientific, or only exploratory, or entirely personal and full of bias. It is called criticism not theory, or it is interpreted politically, as a disguised version of Marxism, or Humanism.

These resistances to qualitative inquiry reflect an uneasy awareness that its traditions commit one to a critique of the positivist project. But the positivist resistance to qualitative research goes beyond the 'ever-present desire to maintain a distinction between hard science and soft scholarship' (Carey, 1989: p. 99). The positive sciences (physics, economics, and psychology) are often seen as the crowning achievements of Western civilization, and in their practices it is assumed that truth can transcend opinion and personal bias (Carey, 1989: p. 99). Qualitative inquiry is seen as an assault on this tradition, leading some positivists to retreat into a 'value-free objectivist science' (Carey, 1989: p. 104) model to defend their position. But these critics seldom attempt to make explicit, and critique the 'moral and political commitments in their own contingent work' (Carey, 1989: p. 104).

The opposition to positive science by the postpositivists and the poststructuralists is seen as an attack on reason and truth. At the same time, the positive science attack on qualitative research is regarded as an attempt to legislate one version of truth over another.

Action Research

In the contemporary period greater use is being made of qualitative evidence in participatory and applied action programs. Life stories, case histories, and personal narratives are often used as key documentary evidence to establish the need for social change. Such materials are also used as proof that an applied action program works. Indeed qualitative (and narrative) evidence lends itself especially well to those applied action programs which stress the subjective, reflexive dimensions of social experience. They further imply that such materials are critical to the implementation of participatory action research as a practical, collaborative, participatory, emancipatory, and reflexive project. First-person narrative texts allow Third World and indigenous persons to share in the ownership of the research endeavor. Such texts anchor research in the context of ongoing community life. They help community members develop a shared orientation toward collective action aimed at addressing social injustice.

Participatory ethno-dramas, forum, and political theater can be used to mobilize community consciousness around an instance of perceived injustice or repression. For example, Brecht's Epic or Dialectical Theatre is deliberately disruptive and political, and thus anticipates the more radical forms of contemporary postmodern, political theater that has connections back to Artaud's concepts of a pure theatre (Birringer, 1993: p. 217). Third World popular theater has been used by 'oppressed Third World people to achieve justice and development for themselves' (Etherton, 1988: p. 991). This form of dramatic representation extends what theater and narrative can do politically.

In Conclusion

The legacies of the present move in several directions at the same time. They all turn on social texts and narratives, their uses and how they are read. The narrative turn in the social sciences presumes that social texts, including recorded or visual texts, interviews, fieldwork notes, transcribed conversations, speeches, film, music, advertisements, personal, electronic, and archival documents, can be rigorously and scientifically analyzed through the methods of narrative analysis.

But Trinh (1989: p. 141) warns us that traditional, empiricist narrative methods represent an approach to storytelling that must be avoided. They turn the story told into a story analyzed. In so doing they sacrifice meaning for analytic rigor. They only hear and read the story from within a set of predetermined structural categories. They do not hear the story as it was told. The goal is to recover these lost stories.

Interrupted Time Series Quasi-Experimental Designs

Richard McCleary, University of California, Irvine, Irvine, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The time series quasi-experiment was proposed initially by Campbell (1963) as a means of assessing the causal effect of a discrete intervention on a social science time series. Although the design had been widely used in the physical sciences, social science applications presented idiosyncratic inferential problems. Addressing these problems as threats to internal and external validity, Campbell (1963) concluded that the time series design was the strongest of the common quasi-experimental designs. Addressing threats to statistical conclusion and construct validities as well as internal and external validities, Cook and Campbell (1979) subsequently concurred with the optimistic validity assessment for the design.

In the simple time series quasi-experiment described by Campbell (1963), a binary variable X_t breaks the time series Y_t into pre- and post-intervention segments of N_{pre} and N_{post} observations. Thus

$$Y_t = \mu + \omega X_t + u_t \qquad [1]$$

The u_t term is a strictly exogenous time series of 'white noise' innovations:

$$u_t \sim \text{iid } N\left(0, \sigma^2\right) \qquad [1a]$$

Scalar parameters μ and ω are interpreted, respectively, as the pre-intervention intercept and the post-intervention change in intercept. Rejecting the null hypothesis

$$H_0 : \omega = 0 \qquad [1b]$$

leads to the inference that X_t affected a change in the intercept of Y_t. The comment label for all quasi-experimental models of this sort is 'interrupted time series model.'

Since most social science time series are nonstationary, and since the effects of social interventions are often dynamic, time series quasi-experiments were not widely used until Box and Jenkins (1970; Box and Tiao, 1975) generalized the simple model [1] to account for nonstationary time series and dynamic effects. The Box–Jenkins–Tiao model can be written as

$$Y_t = f(u_t) + g(X_t) \qquad [2]$$

Here, $f(u_t)$ is an empirically specified *Auto*Regressive *I*ntegrated *M*oving *A*verage (ARIMA) model; $g(X_t)$ is a theoretically specified dynamic transfer model that distributes the scalar effect parameter ω over the post-intervention segment. Component models f and g are constructed by rules that guarantee the existence of inverses f^{-1} and g^{-1}.

The Box–Jenkins–Tiao model [2] controls not only the common threats to statistical conclusion validity, but also some of the most plausible threats to internal validity. Threats to construct validity are controlled by the dynamic transfer component, $g(X_t)$. The common threats to external validity are controlled by replication across settings. Threats to the four validities and the models and methods used to control these threats are illustrated with examples drawn from the applied literature.

Statistical Conclusion Validity

The nine common threats to statistical conclusion validity described by Shadish et al. (2002, p. 45) are spurious inferences associated with misstatements of the Type I and Type II error rates. Type I errors occur when H_0 is true (i.e., when $\omega = 0$) but H_0 is mistakenly rejected. In practice, the Type I error rate is fixed a priori at a conventional level, usually $\alpha = 0.05$ corresponding to 0.95 confidence.

The Type I threats to statistical conclusion validity accrue a consequence of stochastic time series properties, particularly trend or drift and autocorrelation, that are represented explicitly in the $f(u_t)$ component of [2]. For the lag operator $L^k Y_t = Y_{t-k}$, and the difference operator $\nabla^d = 1 - L^d$, $f(u_t)$ can be written as an ARIMA model.

$$f(u_t) = \varphi^{-1}(L)\nabla^{-d}\theta(L)u_t \qquad [2a]$$

Although the $\varphi(L)$ and $\theta(L)$ structures of [2a] were available in the 1920s (e.g., Slutsky, 1937; Yule, 1927), the more general Box–Jenkins–Tiao model was developed in the 1970s. Practical applications required computing resources, of course. Box and Jenkins (1970) described a modeling algorithm which was implemented shortly thereafter. Modern time series software packages included in virtually all-commercial statistical analysis systems evolved from this original modeling algorithm.

If the parameters of the autoregressive and moving average polynomials $\varphi(L)$ and $\theta(L)$ are constrained to the stationary-invertible segment [2a] is solved for the innovation as

$$u_t = \theta^{-1}(L)\varphi(L)\nabla^{-d}Y_t \qquad [2b]$$

If the innovation series estimated from [2b] has the properties [1a], the ARIMA model renders all of the Type I threats to statistical conclusion validity implausible.

The Type II errors occur when H_0 is false (i.e., when $\omega \neq 0$), but H_0 is mistakenly *not* rejected (or even *accepted*). Given a fixed a priori α-error rate, the Type II error rate is optimized by design to be less than a conventional threshold level. For the conventional $\alpha = 0.05$ Type I error rate, the Type II error rate is usually optimized at $\beta < 0.2$ corresponding to statistical power of at least 0.8 (Kendall and Stuart, 1979, Chapter 22).

Compared to the Type I threats, the Type II threats to statistical conclusion validity have received little attention. There are

two reasons for this. First, the Type II threats assume some variation of the Neyman–Pearson hypothesis test (Neyman and Pearson, 1933). In variations of the traditional Fisher significance test (Fisher, 1925, 1955), the Type II threats are undefined. But for the second, assuming a Neyman–Pearson test, most of the Type II threats are related to the length of the time series. Because estimation algorithms rely on asymptotic properties, analyses of short time series may fall below the conventional 0.8 statistical power threshold. Given a long time series, on the other hand, say $N \geq 50$ observations, in practice, the ARIMA model controls both Type I and Type II threats to statistical conclusion validity.

Otherwise, not withstanding the magnitude of the scalar parameter ω – small effects are difficult to detect in even the best circumstances – the statistical power of a time series quasi-experiment is determined by series length, balance, and model adequacy. For constant N and α, the statistical power of a time series quasi-experiment is maximized when $N_{pre} = N_{post}$. Since statistical power is proportional to the absolute fit of the ARIMA model, model adequacy does guarantee that β will fall below the conventional threshold. Nevertheless, spurious inferences attributed to Type II threats to statistical conclusion validity appear rare.

Internal Validity

Although in principle, all nine of the common threats to internal validity identified by Shadish et al. (2002, p. 55) are plausible in the time series quasi-experiment, four of the nine – history, maturation, instrumentation, and regression – account for virtually all of the spurious inferences found in the applied literature. The threats of history and maturation are often made plausible by the relatively long time frame of this design and to the nature of long time series. The threats of instrumentation and regression are often made plausible by the nature of planned interventions. For unplanned interventions, a special case that Campbell (1969) calls the 'natural experiment,' neither threat is necessarily plausible.

When available, a suitable control time series renders the threat of history implausible. Hennigan et al. (1982) uses the time series in **Figure 1** to document an increase in property crime following the introduction of commercial television. In 34 'early' and 34 'late' cities, television broadcasting begins in 1950 and 1954, respectively. Considered separately, history is a plausible threat to the internal validity of both effects. The 'late' effect may be due to an economic recession that began in 1955, for example, and the 'early' effect may be an artifact of the Korean War mobilization. As men were called away to military service and women joined the workforce, homes were left undefended against property criminals. Although history is a plausible threat to the internal validity of each effect, it is implausible for the joint effect of both interventions.

The other three common threats to internal validity are less robust to standard design features. **Figure 2** shows monthly burglaries for Tucson before, during, and after an intervention (McCleary et al., 1982). Prior to 1979, burglaries were investigated by uniformed police officers. When this task was taken over by detectives, burglaries dropped abruptly. Two years later, when the task was transferred back to uniformed officers,

Impact of the introduction of television on crime in the United States: empirical findings and theoretical implications. Journal of Personality and Social Psychology 42 (3), 461–477.

burglaries returned abruptly to pre-1979 levels. While the on–off component of this design rules out the threat of history, the other threats are still plausible. In fact, this effect is entirely explained by differences in the way detectives and uniformed officers keep records; it is an instrumentation artifact. Because interventions often affect the way in which a target phenomenon is measured, instrumentation is always a plausible threat to the evaluation of planned interventions.

Regression threats are also associated with planned interventions but for different reasons. Following a 1955 traffic 'crackdown' in Connecticut, highway fatalities dropped significantly. Examining a long time series, however, Campbell and Ross (1968) show that the reduction was a regression artifact. The 'crackdown' was implemented in 1955 because traffic fatalities in that year were abnormally high; regression to the mean was virtually guaranteed.

The threat of regression is plausible in the Connecticut example because the hypothesis test relied on only $N_{post} = 1$

Figure 2 Monthly burglaries for Tucson, 1975–81. Source: McCleary, R., Nienstedt, B.C., Erven, J.M., 1982. Uniform crime reports and organizational outcomes: three time series quasi-experiments. Social Problems 29, 361–372.

annual observation. Given enough post-intervention observations to model the temporary disturbance, the regression threat is implausible. The Connecticut example aside, no spurious inferences attributed to this threat are found in the applied literature.

The time series quasi-experiment is distinguished from other common quasi-experimental designs by the use of a statistical model to control common threats to internal validity, especially the most plausible threat. Maturation as a threat to internal validity is plausible whenever a time series trends deterministically or drifts stochastically. Because most of the long social science time series exhibit trend and/or drift, maturation is a plausible threat to the internal validity of most time series quasi-experiments.

Figure 3 shows a weekly productivity series from the Hawthorne experiment. From 1927 to 1932, researchers manipulated daily rest breaks and, though not conducting a formal analysis, claimed that rest breaks affected a large, positive increase in productivity. However, formal analyses of these data challenge the original finding. Regressing step functions coded for three 'punishments' regimes, Franke and Kaal (1978) demonstrate that the productivity increases were motivated by fear. The fundamental problem with this interpretation, as well as with the original interpretation, is that the productivity time series exhibits a systematic trend throughout its history. To the extent that the bank wiring room machine operators were becoming more productive over time, maturation is a plausible threat to the internal validity of both interpretations.

To illustrate the problem, the punishment effects estimated by Franke and Kaule are plotted against the productivity series in Figure 3. The effects are collinear with the natural trend of this series. To the extent that a difference equation accounts for this trend, the ARIMA model [2a] renders this particular maturation threat implausible. Reanalysis of this time series quasi-experiment with a difference equation finds a modest but significant effect for rest breaks and no effect for punishment (McCleary, 2000). In general, maturation threats to internal validity are implausible when Box–Jenkins–Tiao models are used to estimate intervention effects.

Construct Validity

Of the 14 common threats to construct validity identified by Shadish et al. (2002, 73), the threats associated with placebo artifacts – experimenter expectancies and novelty and disruption – are plausible in many time series quasi-experiment applications. In true experiments, these threats are controlled by blinding or masking the intervention to subjects and experimenters. In a time series quasi-experiment, the threats are controlled by modeling the effect in a dynamic transfer model for the $g(X_t)$ component of [2]. One popular version of $g(X_t)$ uses a single lagged operator to distribute the effect over the post-intervention segment.

$$g(X_t) = \delta(L)\omega\nabla^d X_t \qquad [2c]$$

If the parameter δ is constrained to $0 \leq \delta \leq 1$, and if d is either zero or one, [2c] includes a subset of models with meaningful and useful interpretations (McCleary and Hay, 1980; McDowall et al., 1980).

Figure 4 shows 50 daily self-injurious behavior counts for an institutionalized patient (McCleary et al., 1999). When the patient is treated with an opiate-blocker on the 26th day, the incidence of self-injurious behavior drops abruptly and stays at the new, lower level for the remaining 25 days of observation. This effect is modeled by setting $\delta = \nabla = 0$ in [2c]. Figure 5 shows the daily counts for a patient who received a placebo on the 26th day instead of the opiate-blocker. This patient's self-injurious behavior also drops abruptly but then returns to the pre-intervention level within a few days. This effect is modeled by setting $\nabla = 1$ in [2c] and estimating a nonzero value of δ.

The visually apparent decaying 'spike' placebo effect in Figure 5 is commonly found in social science applications.

For example, McCleary and Riggs (1982) demonstrate that new laws, whether ultimately successful or not, often produce 'decaying' spikes that have much in common with placebo effects. The ability to model these temporary effects illustrates a salient strength of the time series quasi-experiment. Other common quasi-experimental designs have a difficult time accommodating dynamic effects that are not static and permanent.

External Validity

When Campbell (1957) initially proposed a dichotomous validity system, the common threats to external validity were defined as any that were not obvious threats to internal validity. When Cook and Campbell (1979) expanded the dichotomy to the current four-validity system, the threats to external validity were again defined as the residual set left over after the threats to construct validity had been defined. Shadish et al. (2002, p. 87) take the same position, noting that external validity "concerns inferences about the extent to which a causal relationship holds over variations in persons, settings, treatments, and outcomes." These concerns are not always well described in terms of discrete threats, however, especially as they relate to the external validity of time series quasi-experiments.

As software became more widely available after 1970, applications of the time series quasi-experiment began to accumulate. In evaluation research, effect estimates of replicated social programs often-supported discrepant substantive inferences about the program's effectiveness. Literature evaluating the effectiveness of gun-control legislation is typical in that the published estimates include positive, negative, and null effect estimates (Reiss and Roth, 1993, pp. 255–287). Whereas a small proportion of randomly distributed null effects can be ignored, a broader range of quasi-experimental effect estimates suggests that the inter-replication variance is more important than the general effect itself.

The external validity of several time series quasi-experiments can be analyzed in either of two ways. First, a set of k time series can be defined as vector time series, Y_t

$$Y_t' = \{Y_{1,t}, Y_{2,t}, \ldots, Y_{k,t}\} \quad [3]$$

The vector Y_t' can then be analyzed as a vector ARIMA process (e.g., McGaw and McCleary, 1985). Second, variance in the set of k reported effect estimates

$$\omega' = \{\omega_1, \omega_2, \ldots, \omega_k\} \quad [3a]$$

can be decomposed into components associated with variance in 'persons, settings, treatments, and outcomes.' Since the second approach is a special, restricted case of fitting the set of k related quasi-experiments into a vector ARIMA model; the first approach is preferred. In practice, unfortunately, few time series satisfy the rigid assumptions required for a vector ARIMA model.

Although less general, the second approach is more practical and flexible in most situations. The statistical models used to analyze the set of k related effect estimates, which were originally developed in meta-analysis or research synthesis, decompose the effect variance into components that can be attributed to setting (e.g., place, historical period, and so on), properties of the intervention (e.g., resources devoted to the intervention, mode of implementation, and so on), methodology (e.g., time series properties, dependencies, and so on), and other potential threats to external validity. McDowall et al. (1980) demonstrate this method for combining effect estimates from evaluations of gun control laws; McCleary (2000) uses a similar model for combining effect estimates from the Hawthorne experiment plotted in **Figure 3**.

Future Directions

At this point in its development, solutions to the questions of internal validity have been proposed, tested, and accepted. Solutions to the questions of construct validity for the time series quasi-experiment are resolved by the general Box–Jenkins–Tiao model [2]. Although solutions to the questions of external validity are still too novel to enjoy the same level of consensus, it seems that the currently available solutions will become more widely used and accepted in the near future. All of the unresolved issues relate to statistical conclusion validity. Problems of missing data and short time series (e.g., $N < 30$ observations) pose particular needs.

Otherwise, the consensus view of hypothesis testing is undergoing rapid change in the social sciences. All of the common threats to statistical conclusion validity identified by Shadish et al. (2002, p. 45) are artifacts of what Gigerenzer et al. (1989, p. 106) call the 'hybrid' null hypothesis significance test. As conventions and methods in this area change, fundamental thinking about the threats to statistical conclusion validity is likely to change as well.

Intersectionality

Stephanie G Guittar and Nicholas A Guittar, Valdosta State University, Valdosta, GA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Intersectionality is a methodology and theoretical framework that is designed around drawing scholarly attention to variations in people's lived experiences. Our experiences are driven by our social identification with different dimensions, such as race, class, gender, and sexuality among others, and intersectionality is aimed at making sense of these differences. Intersectionality was born out of a critique of feminist theories as lacking inclusivity, and it has morphed into a variety of approaches designed to investigate previously understudied elements of identity and their connection to disparate social outcomes.

Intersectionality refers to the study of intersecting social categories – such as race, gender, and social class – with which an individual identifies. Intersectionality uniquely addresses a holistic understanding of the lived experiences of an individual within a society. It is the recognition that social outcomes cannot be properly explained by investigating independent social categories and treating them as stand-alone variables. Women are not a monolithic category, and neither are African-Americans. People are affected simultaneously by the social treatment of a multitude of characteristics. Consider the intersection of race and gender – the most storied interaction detailed in early intersectionality literature. This single intersection creates categories of people whose experiences are oftentimes vastly different from groups who share only one dimension (e.g., African-American women and White women) or perhaps none of these dimensions (e.g., African-American women and White men).

The multiple dimensions of our social identities are not easily teased apart. It is essential then to emphasize the synergy of two or more dimensions in order to understand their compound effects on individuals, groups, even social institutions. It is difficult to determine which social category has the most influence over our interactions and experiences because each category is intimately tied to the next – our social demographics operate simultaneously in everyday interactions. We are all the sum of our parts; thus, according to intersectionality, it does not make sense to study each part separately as it would not provide an accurate depiction of our social realities. Studying race, class, and gender as intersecting categories allows us to understand how each of these categories manifests itself within a given social context and in relation to each other.

Intersectionality, as a theoretical framework and/or methodology has been positioned as particularly useful for understanding and explaining the experiences of social categories of people who experience compound disadvantage (e.g., African-American women). Historically, these two categories – race and gender – have been treated as being exclusive of one another. Thus, research was commonly focused on 'women' or 'African-Americans' but rarely on 'African-American women'. Add a third dimension into the mix, such as social class, as you begin to see how complicated it can be to investigate social phenomena without trivializing the experiences of any particular populations. Herein lies the power of intersectionality.

> Fundamentally, race, class and gender are intersecting categories of experience that affect all aspects of human life; thus, they simultaneously structure the experiences of all people in this society. At any moment, race, class or gender may feel more salient or meaningful in a given person's life, but they are overlapping and cumulative in their effects.
>
> (Andersen and Collins, 2012: 4)

Intersectionality was largely born out of a critique of feminist theories as being ill fit to depict or explain the experiences of African-American women. As a theory, intersectionality has continued to be employed most often to investigate the intersection of categories, which result in compound disadvantage; thus enabling researchers to better investigate underserved or marginalized populations. But intersectionality is also being increasingly used to investigate categories of people who experience compound privilege (e.g., White men), as well as categories of people who experience both oppression and privilege on differing dimensions (e.g., gay men).

Intersectional approaches to studying social life are necessary since individuals and groups do not have equal access to scarce resources in contemporary societies. The stratification of society among multiple dimensions has created a social reality where people have such different experiences based upon their ascribed and achieved statuses. At the center of determining our access to valued resources are the polarizing concepts of privilege and oppression. On any social dimension there are groups who enjoy privilege (i.e., unearned advantage) and many other groups who find themselves being pressed or formed into 'lesser' positions in society (see Marilyn Frye's, 1983 essay 'Oppression' for further insight defining oppression).

Without a focus on intersectionality, we would be left with the false sense that all members of a particular category of people (all women, all Hispanics, etc.) are affected equally by various social forces. This is particularly troublesome considering how, in the contemporary United States, members of privileged categories (Whites, men, heterosexuals, people with class privilege, etc.) oftentimes fail to recognize how their privileged position improves their social outcomes. It is as if their privilege is invisible, and this invisibility threatens the ability of privileged groups to recognize how oppressed groups are adversely affected. Conversely, members of oppressed groups firmly recognize and understand that the characteristics by which they are oppressed are intimately tied to their social

outcomes. This disconnect – between those who are privileged and those who are oppressed – can lead privileged people to erroneously believe that they have similar lived experiences to members of disadvantaged groups. This reality was characterized very clearly by Michael Kimmel and Ferber (2010: xiv–xv):

> I first confronted this invisibility in the early 1980s, when I participated in a small discussion group on feminism. In one meeting, a white woman and a black woman were discussing whether all women were, by definition, "sisters" because they all had essentially the same experiences and because all women faced a common oppression by men. The white woman asserted that the fact that they were both women bonded them, in spite of racial differences. The black woman disagreed.

> "When you wake up in the morning and look in the mirror, what do you see?" she asked. "I see a woman" replied the white woman. "That's precisely the problem," responded the black woman. "I see a *black* woman. To me race is visible every day, because race is how I am *not* privileged in our culture. Race is invisible to you because it's how you are privileged. It's why there will always be differences in our experience."

This single interaction between two women characterizes the importance of intersectionality. Two individuals who share a single dimension (in this case, gender) do not experience a unified reality. Their experiences are fractured along the lines of countless other dimensions, most immediately of which is race. Thus, it becomes essential that researchers consider the intersectional nature of our identities.

Hegemonic ideologies further complicate things by erroneously assuming that sex, gender, sexuality, and race are binary terms. One is male or female, a man or a woman, gay or straight, White or Black. Intersectionality challenges this ideology and highlights the variance within each category. Without careful attention to the diversity found within each category researchers will (inadvertently or not) continue to reify false dichotomies. This practice has contributed to the invisibility of intersexuality, transgender, and bisexuality (Lucal, 2008), among other social categories. In fact, many social scientists emphasize that there is greater diversity within a single category of people (e.g., women) than there is between the 'average, typical' members to two different categories (e.g., men and women). Considering this within-group diversity, it is plain to see that there is not just one monolithic lived experience for any social category. Intersectionality allows researchers to better investigate and learn about the unique experience of people in less privileged positions. Before taking a look at contemporary examples of intersectionality 'in action', it is important to delve deeper into the theoretical roots and early formation of intersectionality.

Background and Early Roots

Intersectional analysis stems from a phenomenological and feminist perspective. By employing phenomenological methodology the researcher seeks to understand the lived experiences of individuals through the subjective reality of their experiences in the world. The basic proposition of phenomenology is that reality is socially constructed; that all of our ideas, norms, and beliefs are taken for granted by members of society and hence, not questioned. Phenomenology, as pioneered by Alfred Schutz (1967) is rooted heavily in Weber's concept of verstehen. Verstehen (which is German for understanding) stresses that you must put yourself in another person's shoes if you wish to truly understand their social reality. Phenomenology, then, translates perfectly to intersectionality: in order to understand a person's subjective reality one must simultaneously take into consideration all elements of their social identity (race, class, gender, and the like).

Phenomenological researchers challenge our culturally learned ideas and urge us to question the taken-for-granted beliefs and behaviors that we observe. This last element of phenomenology has obvious methodological implications, and it has become a cornerstone of intersectionality. Consider, for example, that the average person in the United States views sexuality as a 'real' thing – something that can be identified and categorized. Thus, sexuality researchers who are not mindful of their assumptions could enter into a study believing that everyone identifies with a concrete sexual identity. Sexual identities seem like commonplace units for categorizing sexuality, but only recently have sexual identities been used as such. Prior to the 1940s, sexuality was framed almost exclusively as mere behavior and nothing more. Our current practice of categorizing sexual identities emerged in the mid-1940s as the word 'heterosexual' began being used as a way to identify people who are attracted to members of the other sex (Katz, 2007). Fast forward to the present day, and we find that many teens and young adults are bucking these categories, opting out of sexual politics, and stating that they simply like who they like (Yon-Leau and Munoz-Laboy, 2010). Shedding assumptions and taken-for-granted beliefs enables researchers to focus on people's lived experiences and uncover these sorts of revolutionary findings. Phenomenology then encourages the researcher to take the role of a stranger and view the world through someone else's standpoint to understand their subjective reality. This factor positions phenomenology as particularly helpful when researching intersections that do not align with one's own categorical characteristics.

Feminist standpoint theory elaborated on phenomenology by bringing the experiences of women to the forefront. Dorothy Smith (1979) developed feminist standpoint theory, which emphasizes not only that women's perspectives are unique, but also that women live their lives according to a bifurcated consciousness. This concept, similar in form to W.E.B. Du Bois' double consciousness (Du Bois and Edwards, 2007), involves the duality of functioning within a society in which one is viewed as the 'other', while also maintaining one's own lived experience. DuBois' double consciousness is centered on the reality that African-Americans live and operate in two Americas – one dictated by dominant White middle-class ideologies, and another, which is the more authentic experience of African-Americans. Smith similarly emphasized that women's lived experiences are produced along a 'line of fault' within their personal, lived, and reflected-on experience. For women the 'line of fault' is the juncture between what they know, their reality, and the external expectations and culture that exists around them (the patriarchal rules). Hence,

standpoint theory emerged as a way to bring to light the unique experiences of women to a world that had focused purely on men's experiences.

Although the aforementioned works by Smith and DuBois predate the contemporary conception of intersectionality, their focus on the unique experiences of historically underrepresented and consequently oppressed groups is clearly a root of intersectionality. By looking macroscopically and collectively at both scholars' works, we begin to see not only the unique standpoints of women and African-Americans, but the unique experiences of intersectional categories, such as African-American women, African-American men, and White women – all of whom have lived experiences markedly different from the traditionally privileged category of White men. Standpoint theory is not without its critics. The principal criticism related to intersectionality is that standpoint theory is not a holistic approach because it utilizes gender as the main standpoint for women's experience. Intersectional feminists emphasize that race, class, sexual orientation, nationality, and other social categories create different 'standpoints' for women – none of which should be predetermined as more essential than the next. Present-day intersectionality is viewed as a much more holistic and inclusive approach to studying the experiences of individuals in less privileged positions.

The Advent of Intersectionality

Historically, social inquiry has recognized some forms of stratification (namely, gender and race), although the discussion of intersecting layers of stratification did not widely enter the social sciences until the late 1980s and early 1990s. Intersectionality gained recognition as a stand-alone theory and methodology in the late 1980s. Kimberlé Crenshaw (1989) is credited with coining the term 'intersectionality', but it is important to note that many women before her had written about how women of color were marginalized within feminist discourse (Davis, 2008). As early as the mid-nineteenth century, women like Sojourner Truth wrote about the omission of Black women in civil rights movements. Feminist theorists, such as Patricia Hill Collins, Barbara Smith, bell hooks, Lynn Weber, and Audre Lorde, among others have contributed to the development of intersectionality to include the unique experiences of minority women among feminist thought.

Intersectionality arose from a criticism of feminist theories for omitting women of color in feminist research or including "hand picked Black women's voices to avoid criticisms that they are racist" (Collins, 2000: 6). Intersectional theorists argued that feminist perspectives inaccurately depicted the experiences of *all* women as a collective, shared experience. While feminist theorists brought awareness to gender inequality, they typically overlooked other forms of oppression (e.g., racism, classism) that are equally central to the experiences of minority women. In a similar vein, minority women were historically left out of academic discussions of race. Thus women of color largely existed on the fringes of research on two of the central most elements of their identity (i.e., gender and race). The experiences of women of color were insufficiently represented by feminist and racial discourses, and intersectionality emerged as a way to counter this relative invisibility. A 1993 article by Bernice Barnett serves as an excellent example of how early intersectional research worked to mend minority women's invisibility on both fronts. Her work details the invisibility of Black women's contributions to the civil rights movement, and it showcases the power of employing an intersectional methodology in order to highlight the unique experiences of a particular category of people.

Intersectionality gained steam throughout the 1990s as a key perspective for unlocking the interaction between social categories, such as gender, race, and social class (along with other dimensions) that permeate people's lives. More specifically, intersectionality began to emphasize "the outcomes of these interactions in terms of power" (Davis, 2008). Power, in a Weberian sense, is the probability that one actor within a social relationship will be in a position to carry out his or her own will despite resistance. Through intersectional analyses, one is able to see how social categories work simultaneously in conjunction with one another to produce a compound influence that can limit or enhance an individual's ability to carry out his or her own will. Thus, intersectionality is essential to understanding how power operates in a multicultural society. Grouping all women into one category, as prior feminist writings had done, is problematic. It does not enable researchers to conceptualize the power struggles that adversely affect women, racial minorities, sexual minorities, and the underclass, among others.

Patricia Hill Collins is largely credited as the chief expert on intersectionality – beginning with her seminal work *Black Feminist Thought* (2000). Although Collins – whose work garners much more attention below – wrote most heavily about intersectionality as it relates to Black women, intersectionality research has expanded far beyond the dimensions of race and gender. Intersectionality is clearly applicable to every person or group in society. A poor, White, gay woman may be privileged because of her race but she simultaneously experiences oppression as a result of her social class, sexuality, and gender. Similarly, a Black man may be privileged because of his gender but he experiences disadvantages due to his race. Therefore, using single categories to describe an individual's experience neglects all possible forms of oppression or privilege that one can experience. Intersectionality can even be employed to critique 'majority' groups and emphasize different dimensions of privilege.

Some scholars speak of intersectionality as a theory, others as a concept, and others as an analytical approach (Cole, 2008; Davis, 2008). As a theory, it is vague in that there is not a clear-cut methodology to properly test it. There is not a consensus on the social categories that should be analyzed (beyond race, gender, and social class) or where the line should or could be drawn. On the other hand, its vagueness and the vast number of categories that can be intersected reconcile the gaps between critical feminist theory and postmodern feminist theory. Intersectionality challenges the complexity, the distinctiveness, and the entirety of the wide range of social categories. No social category is binary, and intersectionality as an analytical tool allows researchers to study the effects of these fluid and complex categories on all lived experiences. Such is a major reason why intersectionality has become so central to contemporary applications of queer theory, feminist theory, and critical race theory.

The Matrix of Domination

> Oppression and resistance remain intricately linked such that the shape of one influences that of the other. At the same time, this relationship is far more complex than a simple model of permanent oppressors and perpetual victims. Another way of approaching power views it not as something that groups possess, but as an intangible entity that circulates within a particular matrix of domination and to which individuals stand in varying relationships.
> (Collins, 2000: 274)

Collins conceptualizes intersectionality as a matrix of domination. She uses her intersectional framework to illustrate the ways in which each demographic category intersects with structures of power and privilege to form unique lived experiences for various group. In the matrix of domination, there are multiple interlocking levels of privilege and oppression that stem from our stratified positions within various elements of US society. Collins initially focused almost exclusively on the empowerment of African-American women through an understanding of the multiple oppressive forces of gender and race – which work together to undermine individual and collective effort. She has since broadened her theoretical use of the matrix of domination to encompass all groups formed by the intersections of race, class, gender, nationality, and sexuality. One is not simply oppressed or an oppressor; privileged or disadvantaged. Oppression and privilege do not play out in simple binary terms (of either having it or not), they are instead forces to which all individuals have differing relations. The social structuring of race, class, gender, and sexuality "affects individual consciousness, group interaction and group access to institutional power and privileges" (Andersen and Collins, 2012: 5). Through the perspective of a matrix of domination, one social category is not more important than another. One cannot be more important than another at all times. As mentioned earlier, one can be more salient than others at one time but it is the combination and the cumulative effect of all of our privileges and disadvantages that shape our experiences. We are never viewed as just one 'something'. A woman is never viewed as *just* a woman; there are other social categories, such as her race, class, sexuality, nationality, education that will affect interactions, and her access to power and privilege.

Intersectionality: Different than Studying Difference, Diversity or Multiculturalism

Patricia Hill Collins makes a great distinction between intersectionality and the study of difference, diversity or multiculturalism. At first, intersectionality may seem intuitive – as in 'how is this a new perspective?' Have we not researched race, class, and gender for decades? While race, class, and gender have been used as 'variables' in quantitative studies, and plenty of feminists have studied the experiences of women, intersectionality is not as simple as it sounds. To study the intersections of race, gender, and class, one must surpass the simple task of comparing experiences of difference. When individuals think of the experiences of those who are not like them, they may simply engage in a comparative analysis. For example, a White male listening to the experiences of a Latino male may think to compare the experiences of Latino men to other Latino men from the Caribbean, Central, or South America. In doing so, the White male has grouped the Latino male experience as one based strictly on his ethnicity and assumed it to be comparable to others of the same ethnicity. Engaging in this type of comparison overlooks how an individual's experience can be shaped by nationality, racial variations within an ethnic group, and social class (among other categories) that represent a position in a system of power, where a person can be privileged in one category and oppressed by others. Though learning about different groups is a step in the right direction toward enhancing knowledge of others' experiences, it is important to recognize that there is more to the experience than simply the influence of one social category; in this case, ethnicity.

Comparative analysis can also lead one to compare how one group's oppression is similar to other oppressed groups. For example, some have compared the marriage equality movement to the civil rights movement. While racial minorities and sexual minorities have both experienced oppression in our society, comparing their oppression is not an appropriate approach because it overlooks the various power mechanisms at play for each member of these groups. Not to mention the civil rights movement of the 1960s was not focused solely on race, but on equality as a whole. Comparing groups also lends itself to setting up a hierarchy where one group's oppression is ranked against the others as if being the most oppressed somehow earns more attention or empathy. It can also lead to a comparison to the dominant group, the 'norm' that automatically classifies those who differ as 'abnormal' and creates stigma. Engaging in comparative analysis of the experiences of oppressed groups does not accurately describe or analyze the experiences in terms of the interlocking mechanisms of privilege and oppression.

Collins also points out that intersectionality is different from studying diversity. Diversity has become a popular word in our society, and increasing diversity and inclusion has become a primary goal for many institutions. Diversity initiatives aim to increase awareness about different cultures, races, and ethnicities. But in doing so the underlying message is that, while we may look different, beneath it all we are all the same. Thus pure diversity-based approaches risk completely overlooking the inequalities that various minority groups experience as a result of their position in society. When the idea of 'beneath it all, we are all the same' is promoted, race, class, and gender are understood as strictly aesthetic differences between us rather than vehicles of opportunities and constraints within the structures of power in our society. Collins states:

> The very term diversity implies that understanding race, class, and gender is simply a matter of recognizing plurality of views and experiences in society—as if race, class, and gender were benign categories that foster diverse experiences instead of systems of power that produce social inequalities.
> (Andersen and Collins, 2012: 8)

Intersectionality analyzes experiences based on the interconnection of ethnicity, race, class, gender, nationality, religion, sexuality, and any other social categories that situate one's experience in relation to power in society. This focus on the differential influences of power and privilege set

intersectionality apart from studies of diversity and difference. From Collins' perspective, the matrix of domination is the most accurate approach to analyzing intersectionality "because of its focus on structural systems of power and inequality" (Andersen and Collins, 2012: 9).

Intersectional Methods and Analysis

By now, the importance of researching intersectionality should be obvious. While many scholars agree that intersectional research is needed, few scholars have outlined a clear methodology and analytical strategy to conduct intersectional research. Such is a major criticism of intersectionality. There seem to be a number of common themes for intersectionality scholarship that make it difficult to narrow down exact methods to conduct intersectional research. In this section, some of the approaches that have been discussed in the literature are summarized. McCall (2005) outlines three approaches to studying intersectionality: anticategorical, intracategorical, and intercategorical (although she emphasizes that not all intersectional research fits nicely into one of these approaches). These are not new ways of studying intersectionality but place the current intersectional methodologies into three categories.

The anticategorical complexity approach, as the name suggests, rejects the labeling of any particular category. The meaning of any social category, such as race, gender, or sexuality is highly contextual and socially constructed. Weber (1998: 16) states, "Although they [race, class, gender, and sexuality] persist throughout history, race, class, gender and sexuality hierarchies are never static and fixed, but constantly undergo change as part of new economic, political, and ideological processes, trends, and events." Since these categories are never static, any category can be challenged and eventually become insufficient. For example, it is no longer sufficient to categorize individuals as 'gay' or 'straight'. There are numerous sexual identities, some of which are depicted as falling along a sexual continuum (e.g., bisexual), and others, which defy traditional gender dichotomies (e.g., pansexual). Further, some contemporary youth reject any sexual identity labels. The same way that White and Black are not sufficient racial categories, the same can be said of categories for other forms of stratification. Categories are social constructs that develop and evolve over time. Therefore, the anticategorical complexity approach focuses on the avoidance of placing individuals into preformed categories. This approach is similar in vain to a poststructuralist perspective, which opposes binary labels as they suggest a hierarchy or opposition between categories. Poststructuralist researchers are encouraged to deconstruct the labels to understand the realities of individuals who may not ascribe to such labels. Considering the proliferation of progressive sexualities that defy simply categorization, many practitioners of queer theory have opted to utilize anticategorical complexity approaches in contemporary scholarship.

The intracategorical complexity approach, also referred to as the microreductionism approach (Walby, 2007), has managed the complexity of intersectionality with the use of case studies, along with ethnographic and narrative methods, to analyze the intersections of multiple social categories. Many researchers have utilized case studies to identify 'invisible' populations not commonly represented in the literature. In doing so, researchers shed light on these 'new'" groups, but by utilizing case studies of individuals in these groups they uncover the differences *within* the group (hence the *intra*). This approach can yield valuable qualitative insight on understudied group, but this approach can be problematic because it has "become a strategy of seeking out ever finer units for analysis, in pursuit of a pure intersecting category. But, there are no pure groups; there are always more forms of difference" (Walby, 2007: 457).

In the continued pursuit of carving out new intersectional methodologies, many scholars find themselves researching 'storied' social categories that seem to have been reified as concrete entities by prior research. For example, categories such as African-American women and Latinas have been extensively researched and therefore serve as excellent starting points in terms of studying intersectional dynamics. This approach to intersectionality, dubbed intercategorical complexity, "requires that scholars provisionally adopt existing analytical categories to document relationships of inequality among social groups and changing configurations of inequality along multiple and conflicting dimensions" (McCall, 2005: 1773). Some scholars view this approach as contradicting the design of other forms of intersectional research. However, McCall emphasizes that this approach is not contradictory – it simply involves analyzing relationships of inequality between two or more social groups instead of analyzing complexities within a single social group. In other words, this approach is helpful in ascertaining the closing or widening of gaps in social outcomes that may exist between groups. For example, an intercategorical analysis of race and ethnicity would start with broad categories like Black and White, Hispanic and non-Hispanic. Analyses could then investigate intergroup differences along more detailed social groups that lie at race/ethnicity intersections (e.g., White Hispanics, Black Hispanics, White non-Hispanics, and Black non-Hispanics). Other dimensions, such as social class or sexuality can be added, which result in increased intercategory comparisons. These comparisons may appear rather reductionist when viewed as individual comparisons, but their combined analyses yield detailed intersectional findings that are quite holistic once pieced together.

Intercategorical complexity has been employed as a helpful approach for intersectional inquiry in various quantitative studies. Considering the structural reliance on the use of social categories in most quantitative research, this approach enables finite scrutiny of intersectional differences between group outcomes. Rather than using social categories (race, gender, class) as stand-alone independent variables, the use of 'interaction terms' or 'interaction effects' enables researchers to engage in intercategorical analyses to learn more about the combined effects of various social attributes. An example of this can be seen in a recent article by Guittar and Pals (2014), where the researchers investigated the combined effects of gender, race, and religiosity on attitudes toward homosexuality. One could argue that such a research design treats social categories as essentially different. But the use of interaction terms in ordinary least squares (OLS) regression analyses (which include the use of various control variables) can isolate extraneous influences, which oftentimes result in the appearance of 'real' differences rooted in race or gender. In the Guittar and Pals study they found that purported intersectional differences between race/gender categories (Black men, White

women, etc.) were not about race or gender itself, but about religiosity and gender role beliefs among these intersectional categories of people.

Intersectionality is still a young, evolving methodology and theory for studying unique experiences that lie at the intersection of various social categories. From an original focus on the intersection of race and gender to a contemporary emphasis on broader topics, such as the transcendence of categorization, intersectionality aims to draw scholarly attention to the variation in people's lived experiences. People have layered identities rooted in privilege and oppression, and these identities contribute to disparate social outcomes and unequal access to valued resources. Intersectionality empowers some scholars to emphasize within-group variation while enabling others to emphasize across-group differences in social outcomes. While the approaches to intersectionality are quite varied, they all hold consistent the notion that our identities are complex, and that we must be ever mindful of our relationships to numerous structures of power.

Intersectionality and Crime

Abstract

Intersectionality, coined by Crenshaw (1989), is a framework utilized across a broad range of social sciences to explore how individuals within multiple systems of oppression have unique experiences and responses to those experiences. Within the study of crime, intersectionality has primarily been utilized by feminist criminologists to identify how and why women with different social statuses or from different racial or ethnic backgrounds have different levels of criminal involvement and experiences with victimization. This article briefly reviews the state of research utilizing intersectionality frameworks to examine crime and victimization.

Introduction

The concept of 'intersectionality' as relevant to the study of power differentials between groups and individuals was first raised in the 1980s. Researchers interested in a variety of status defining variables, such as race, gender, and class, recognized that certain groups of individuals crossed lines, or categories, of oppression – experiencing oppression based on more than one social category or socially benefiting because of statuses attained across more than one category. Crenshaw (1989) first coined the term 'intersectionality' in her efforts to portray how laws may actually omit particular groups experiencing discrimination (or oppression). Since this time, the use of intersectionality to formulate research questions and to theorize about relational oppression has expanded. Studies employing intersectional frameworks can be found across a wide range of disciplines, such as political science, social work, public policy, public health, gerontology, psychology, and sociology (Best et al., 2011; Daly, 1997). While a number of scholars have recognized the impacts of specific structural positions denoted by membership in specific categories (such as race, sex, and class) in the field of criminology, it is only recently that scholars specifically and deliberately have begun to apply intersectional frameworks to develop and explore questions within the fields of criminology and criminal justice.

Its relatively new stature within criminology and criminal justice yields a framework that has been inconsistently utilized, and which, when utilized, is associated with a variety of terms theoretical questions, and methodological approaches. This article explores the use of 'intersectionality' in criminology and criminal justice. We start with a description of intersectionality, examining its roots, key methodological discussions, and key issues. We then review criminal justice and criminological research that has utilized intersectional approaches, both overtly and through less deliberate tests of intersectionality.

Background

Conceptually, the ideas behind intersectionality grew out of criticisms predominately offered by black feminists critical of mainstream feminism for assuming that all women had shared experiences. Such critiques declared that the focuses of feminism generally reflected the desires and needs of middle-class women, signally a lack of understanding that black women, historically and today, have significantly different experiences when compared to their white counterparts (Sokoloff and Burgess-Proctor, 2011). Movements within black feminism and throughout women's studies increasingly revealed that not all women are the same. Hence, predicating research, policies, and programs on the assumption that women stand as a single analytical category was argued to be a flawed approach (McCall, 2005). Importantly, it was recognized that simple additive models that included gender and race missed the unique and complex experiences of black women, poor black women in particular, who occupy a unique social position generated by overlapping systems of oppressions (Burgess-Proctor, 2006; Collins, 2007). As Bernard (2013: pp. 3–4) noted, positions held by marginalized women who occupy multiple subjugated statuses yield "vulnerabilities that … can be difficult to measure." While race was highlighted as a crucial factor distinguishing women within early works (Crenshaw, 1989; but see also Collins, 2007), additional structuring factors, such as class or age, were soon recognized as influential in shaping experiences. To date, however, the majority of intersectionality research still primarily considers gender, race, and class, which are treated as the key master statuses comprising the axis of oppression.

While intersectionality generated a great deal of discussion and debate within gender studies and legal feminist discussions, intersectionality works in criminology lagged. This is not to say that criminological research has not examined the multiplicative effects yielded for those oppressed by race, sex, and class, but rather that claims of theory building through intersectionality or research driven by intersectional methods have not been the norm. Instead, while early criminological studies produced by researchers such as Daly (1989), Messerschmidt (1993), and Miller (1998) clearly reflected intersectionality as foundational in questions, approaches, and methods, explicit reference to an 'intersectional framework' per se was not always highlighted. Recent years have seen a rise in intersectionality references in research on crime and victimization.

As with research in other fields, in criminology, the primary use of intersectionality as a framework has been to provide a tool that ensures greater understanding of the systems in place and processes that work together to create inequality for certain groups and subgroups in society. While research in

mainstream criminology does at times reflect this understanding, more overt discussions of unique statuses created through the intersections of multiple oppressed categories is most likely to be found by researchers interested in the study of women and crime. As with other fields, the primary master statuses considered are sex, race, and class; the assumption is that the intersections of inequalities generated by these socially structured systems yield multiplicative, not simply additive, results that predict not only offending but also victimization.

Given broader discussions of intersectionality, and the debate about its usefulness for theory building, as well as for the development of research strategies, it is useful to consider how intersectionality is linked to theoretical developments in the study of crime, as well as how it has been employed to design research that is aimed at understanding the multiple positions of women. Notably, authors across numerous fields have described intersectionality as a framework, or paradigm, useful for theory building and testing rather than as a theory itself (Davis, 2008).

Theoretically, intersectionality is used to stress the need for criminological research to reconsider the broad categories frequently utilized to understand criminality within extant theories. As well, discussions of identity and systems that externally structure development of identities within specific groups or systems have emerged (Messerschmidt, 1993). Further, the need to develop multilevel explanations for crime and responses to crime are underscored by intersectional research, as systems of oppression do not work independently, but rather interactively, to produce various planes of oppression (Bernard, 2013; Collins, 2007). Finally, this perspective focuses attention on the role of relationships between individuals; hence, theories that recognize the role of relationships in generating and reflecting power differentials and resultant influences on crime and victimization are prime candidates for expansion through intersectional frameworks (Sokoloff and Burgess-Proctor, 2011; Bernard, 2013).

Methodological Approaches and Intersectionality

Because the foundation of intersectionality is in the study of women and the law, use of this framework by legal scholars is unsurprising. Legal research has explored the utilization of law to understand and promote human rights for women, immigrants, children, and other groups with minority statuses, marriage and other rights for same-sex couples, and to meet the needs of adults and children with disabilities (Best et al., 2011). Ultimately, legal scholars use intersectionality to examine how the law, by ignoring intersectional statuses, may actually exclude groups who exist in multiple oppressions because such groups are not represented within many legal protections (Conaghan, 2009). The effective portrayal of the problems facing black women by Crenshaw (1989) since has been applied to others who experience multiple oppressions to examine how intersecting oppressive statuses influence treatment under the law and how the law can be utilized to redress inequities.

With acceptance of intersectionality extending outside of legal scholarship came questions of how this framework could be utilized in research to address additional theoretical and policy questions. Understanding the broader picture of how intersectionality is linked to research methodologies is important for any review or utilization of this framework. McCall (2005) provided a comprehensive analysis of how using intersectionality requires careful consideration in methodological approaches due to the complexity of the social phenomenon that it seeks to address. Acknowledging that a broad array of methodologies are utilized in intersectional research, McCall classifies these methodologies based on forms that intersectionality may take, which she references as anticategorical complexity, intercategorical complexity, and intracatagorical complexity.

According to McCall (2005), intersectional research was initiated within an intracategorical framework, which recognizes, but is critical of, stable, enduring social categories such as race, sex, and class. Intracategorical research primarily is concerned with identifying groups that emerge at specific intersections (such as sex and race or race and class) and highlighting the importance of shared points of oppression. Research conducted in the intracategorical approach, while conceding that there are such social categories, ultimately questions the validity of the processes through which social boundaries are created and defined. To accomplish this, researchers may select a broad category – such as women – then seek to identify differences between women that occur on the basis of other social categories (class or race, for instance). Intracategorial research frequently takes form through narrative essays, case studies, and studies of single groups, as well as through ethnographic research.

Anticategorical research is more keen to recognize the complexity of social life and, more specifically, socially identified categories that yield or reflect inequities. Researchers utilizing the anticategorical approach, according to McCall, question the viability of categories, and ultimately deconstruct categories, because they recognize that individuals are not only members of multiple oppressed categories but also that such membership is both fluid and relative. Such is the case, for example, for scholars interested in research on transgendered individuals, who argue that gender contains many more categories than just male and female or masculine and feminine. McCall (2005) links methodologies such as geneology and new ethnography to this category of intersectional study.

Finally, intercategorical complexity falls on the more conservative end of the spectrum. Researchers employing an intercategorical approach recognize and accept extent social groups and categories associated with oppressive experiences. Researchers from this frame are interested in the differences between categories and the relationships present between the oppressed and the powerful. They are particularly interested in how interactions between socially situated groups are created, maintained, and managed by both those in power positions, as well as those experiencing inequality. Scholarship from this vein is the most likely to employ quantitative methods alongside qualitative methods; however, with the addition of complexity added by the intersectional approach, researchers must employ more sophisticated methodologies. More specifically, quantitative research from an intercategorical approach is punctuated by interaction effects (rather than simple additive models), multilevel modeling, ecological models, or contextual approaches because only by jointly

examining structural categories can the effects of intersections be adequately examined (McCall, 2005).

McCall (2005) concludes that these organizing categories are not the only way such research can be classified; rather, McCall recognizes her scheme may be incomplete, arguing that researchers should not accept these categories within her classification scheme as immutable, but rather that research can, and likely should, reach across these different frameworks to more fully examine questions and yield more comprehensive conclusions.

While others have discussed the methodological approaches to the study of intersectionality, McCall's (2005) classification schemes have garnered substantial acceptance across literatures, and her caveats are well attended. Indeed, most research addressing intersectionality seems to employ a mixed methods approach with qualitative methods considered key to understanding intersectional experiences identified by quantitative approaches.

Intersectionality and Criminality: Theoretical Links and Developments

As previously noted, within criminology, the use of intersectionality as a framework is relatively recent, and primarily is utilized within feminist criminology to enhance understanding of female criminality and victimization. Since early critiques that social scientists, and criminologists in particular, neglected women in the study of deviance, the study of women and crime has significantly increased. Daly and Chesney-Lind (1988) called for researchers interested in gender and crime to address a number of key questions, two of which have served as the foundation of most research in this arena. First, researchers have begun to explore the viability of traditional criminological theories for enhancing our understanding of female criminality, known as the 'generalizability question.' To a lesser degree, researchers have examined the 'gender ratio' question – searching for explanations of the gender gap in criminality (Daly and Chesney-Lind, 1988). More recently, however, criminologists have specifically begun to explore differences in criminality that exist 'within' sex categories, as well as between, yielding work that identifies gendered pathways into offending (Daly, 1989; Messerschmidt, 1993; Miller and Mullins, 2006), as well as work more directly nested in an intersectional paradigm (see discussion in Burgess-Proctor, 2006).

Today, intersectionality is inherently embedded in the feminist criminology, which Miller and Mullins (2006: p. 221) suggest is primarily linked to providing 'narrower, more focused explanations of contexts and situations,' or middle-range theorizing. As such, when a broad review of the literature is taken, one can identify research that reflects intersectional analyses, even though such research may not explicitly reference intersectionality at the outset. Researchers have drawn from intersectionality to reexamine traditional theories and to hone concepts such as class within such theories. As well, research on 'doing identity' frequently utilizes intersectionality. Moreover, intersectionality exists at the foundation of multilevel explanations for crime, as well as research aimed at uncovering how relationships between individuals affect criminality. Finally, more recent research drawing from intersectional approaches has pointed out the need to understand the intersections of crime–victim statuses in generating unique offender subgroups.

Traditional Theories of Crime and Intersectionality

Intersectional research that has led to the reconsideration of broad categories within traditional criminological theories has yielded conclusions that this framework is useful for identifying weaknesses in such perspectives, as well as for suggesting improvements. For example, using quantitative analyses, Simpson and Gibbs (2006) explored interactions between race, gender, and class within traditional criminological models to determine if an intersectionality framework would identify differences in effects of theoretical constructs not yet identified. Their findings indicate that while traditional theories are useful, dissecting constructs using this framework identified differences that should be further explored.

Likewise, Bernard (2013) delved into Merton's strain theory drawing on an intersectionality framework to demonstrate how concepts from this perspective are improved with consideration of differences within subgroups. Bernard noted that Merton, in his version of strain theory, suggested that crime is the result of strains produced by feelings of frustration yielded for particular segments of society who accept the goal of success but do not have available legitimate means to attain these goals. Bernard extended Merton's discussion by arguing that women, in contrast to men, may be more likely to become involved in criminality as a result of the constraints they experience rather than strains; she noted that women who exist under multiple vulnerable statuses respond to oppressions according to the social contexts they occupy. She concluded by highlighting that 'doing identity' reflects how groups who occupy intersectional statuses adapt to their unique positions.

A broader exploration of multiple criminological theories generated the conclusion that while traditional criminological theories are useful for understanding broad differences in offending across boys and girls, important differences exist within these categories for which such theories cannot account. For example, Katz (2000) found differences in correlates of delinquency between black and white females. Specifically, among females, black youths were more delinquent when they reported feelings of alienation, while white delinquent girls were more likely to report feelings of depression.

Notably, and perhaps not surprisingly, most feminist criminologists' applications of intersectionality to improving theories of crime have focused on gender and race. Bell (2013), however, is critical of the categories of race that have been the focus of most of this research, as it is largely limited to comparing white and black offenders. She draws on intersectionality to examine the life course perspective, with a focus on determining whether the intersections of multiple oppressions are more or less salient in generating delinquency and crime depending on life course stages. In contrast to other research, she considers the status of Hispanics, as well as whites and blacks. Her results yielded support for the application of intersectionality, with the intersection of race and gender playing a key role for young adults, but not for juveniles. Specifically, among juveniles race and gender had direct effect, with boys more likely than girls to commit delinquent offenses

and blacks more likely than whites and Hispanics to be involved in delinquency. However, no race × gender interactions yielded significant results. Among young adults, in contrast, Bell (2013) reported that race and gender did significantly interact, and moreover, the race effect was enhanced by broadening the categories considered. Specifically, young adult males were more likely than not to be offenders, and young Latino men were more likely to be involved in property crimes than to be criminally uninvolved (Bell, 2013: p. 114). All females were less likely than males to be offenders when they were young adults.

In sum, research generated from an intersectionality perspective supports the need to consider how individuals positioned in multiple oppressive statuses may not fit the models generated by traditional criminological theories. Furthermore, this emergent literature yields the conclusion that patterns identified through quantitative analyses could be further understood by exploring differences using qualitative research. This approach, as suggested by McCall (2005), would be useful for improving our knowledge and further honing our theories.

Considering Intersectionality in 'Doing' Identity through Crime

Another branch of intersectionality research recognizes that managing multiple social oppressions leads some individuals into criminal behavior as a mechanism for achieving success. This branch of intersectionality is primarily associated with the works of Pat Carlen (1988) and James Messerschmidt (1993), each of whom associates intersections of gender and class with criminality, with the former focusing on criminality of women, and the latter on male participation in crime. Each scholar recognizes that one's position in larger social structures leads to different forms of relations at an individual level. These interactions are the basis in which individuals 'do identity' (Bernard, 2013), and it is the context in which these interactions occur that dictates whether an individual's behaviors are deemed as appropriate or deviant. The concern is with how individuals 'do gender,' or act in ways considered appropriate in any given situation based on one's sex category.

Carlen (1988) draws on the association between class and gender to examine women's participation in crime by linking failure to achieve 'success' in one of these two domains to criminal participation. She describes gender norms for women as striving to have happy and strong families with men who are the primary breadwinners. According to Carlen, women's participation in crime results when either the woman must generate their own income (violating the 'class deal') or when she is unable to develop or maintain a happy family life and/or relationship (violating the 'gender deal'). Notably, in her work, Carlen recognizes the importance of multiple statuses and does not position either class or gender as more important or relevant than the other, rather it is the process of navigating the experiences generated by unique positioning of multiple oppressions that is of interest.

While Messerschmidt (1993) also is interested in class and gender, in contrast to Carlen his position is that crime is one way marginalized youths have to 'do' masculinity when other, legitimate, routes for demonstrating masculinity are unavailable. Messerschmidt argues that masculinity may be achieved in different ways depending on the social context in which an interaction takes place. Researchers continue to build on Messerschmidt's work in efforts to deepen our understanding of factors that influence behaviors linked to 'doing masculinity.' For example, Shade et al. (2011) explore the role of fatherhood in 'doing masculinity' for adolescent males involved in the juvenile justice system, concluding that understanding life course stages and experiences within intersectional contexts is important for the development of policies and programs to reduce teen parenthood.

Miller (1998) extends 'doing identity' work extensively across numerous studies. Like Messerschmidt and Carlen, Miller asserts that gender is achieved situationally, as males and females engage in behaviors that establish their femininity and masculinity. For example, while Miller (1998) notes that males and females cite similar reasons behind their involvement in robbery, such as thrill seeking and as a way to obtain money or other material goods, the methods they utilize distinctly reflect 'doing gender.' Specifically, men's use of physical force and targeting of male victims in the commission of robbery allows them to demonstrate their masculinity. Female robbers, in contrast, varied their methods by their victim; women are likely to target other women as victims – citing less need for force or use sex if they are robbing a male victim. Likewise involvement and activities for boys and girls involved in gangs reflect situationally defined ways of 'doing gender' (Miller, 2008).

Reviewing criminological work on 'doing identities' highlights the usefulness of intersectionality for examining not only microlevel intersections but also intersections that occur at the macrolevel and generate unique settings, contexts, and groups relevant to understanding crime rates as well as criminal behaviors. As described by Collins (2007), macrolevel influences also intersect, or interlock, generating group level positions associated with multiple factors that structure experiences, as well as available choices and social and personal capital for those who inhabit those spaces.

Intersectionality and Crime at the Macrolevel

Less criminological research has utilized intersectionality to examine macrolevel differences in crime. This is surprising given the theoretical frameworks that call attention to macrolevel phenomenon. For example, a number of criminological theories consider class (anomic, strain, social disorganization) and race (social disorganization, racial threat) at the community level. However, it is notable that macrolevel theories rarely consider the impacts of gender. Bell (2013) is critical of this omission, citing research that depicts sex differences in criminality within communities; in marginalized communities, it is noted that while black women may have higher offending rates than white women, their rates of offending are lower than those of black men. Hence, even at the macrolevel, within-sex differences exist.

Haynie and Armstrong (2006) and Parker and Hefner (2013) utilized intersectionality to examine rates of domestic violence and homicide, paying particular attention to the victims of these offenses. Each study concluded that

drawing on such a framework yielded findings of interest. Specifically, in reviewing homicide rates of cities, Haynie and Armstrong (2006) determined that not only are gender and race separately strong predictors, unique findings are uncovered when race and gender are considered together. For example, while structural disadvantage was positively associated with black and white females' homicide rates, its association with the former was stronger. However, when comparing the effect of structural disadvantage within race, its association with male homicide rates was stronger than for females among whites but stronger for females' than males' among blacks. Likewise Parker and Hefner (2013) examined intersectionality at the macrolevel, specifically exploring the effects of economic disadvantages, family structure, and changes in incarceration and domestic violence policies with a focus on those who experience multiple disadvantaged statuses – specifically race and gender. They also determined that the intersectional framework yielded a more elaborate understanding of the unique positions and disadvantages held by black women in our society, as economic deprivation was more salient for understanding the homicide rates of black women than of white women.

Using Intersectionality to Understand System Involvement

The links between race, class, sex, and offending have long been explored, and the recent shifts to examining their intersecting effects for those experiencing multiple oppressive statuses clearly point to the need to further utilize an intersectionality framework to enhance our understanding of offending. Just as these and other variables have been identified as salient to understand offending, it also has been recognized that they impact how an offenders and victims experience the criminal justice system. Steffensmeier et al. (1998) outlined the focal concerns model for enhancing our understanding of judicial sentencing decisions and the ways that race, gender, and age both separately and together impact such decisions. According to the focal concerns perspective, it is those who reside at the intersection of multiple statuses of inequality, namely race, age, and gender, who are perceived in the justice system as the most likely to put society at risk. This model purports that judges make decisions based on three focal concerns: offender blameworthiness and amount of harm experienced by victim, community protection, and individual and organizational practical implications of sentence outcomes. Because judges frequently have little contact or time to observe offenders as a result of the plea-bargaining process, they may draw on additional information from experiences and stereotypes to aid in their decision-making process. This yields the targeting of young, black, male offenders as those who experience more severe sanctions. Their research (Steffensmeier et al., 1998) supports the focal concerns model; the effects of race were dependent on the gender and age of the offender, the effect of gender was dependent on race and age, and the effect of age was influenced by gender and race. Qualitative data reflecting judicial perceptions of offenders based on race, gender, and age further explicated findings, supporting the focal concerns assumption that young black male offenders were perceived as more dangerous than other groups, as well as the belief that incarcerating women and older offenders, who are seen as less blameworthy, yields higher social costs. Extensions of this framework to examine bail (Demuth and Steffensmeier, 2004) and parole decisions (Huebner and Bynum, 2006), along with additional studies of sentencing, provide further support that these variables, and specifically different combinations of them, yield interactive rather than simple additive effects.

The focal concerns perspective reflects the intersectionality framework, with findings that not only do multiple statuses interact to create unique positions affecting identities and resultant experiences, but also to influence others' reactions to them. Indeed, support for the focal concerns perspective indicates that system officials look not simply at singular characteristics when making decisions but rather simultaneously consider multiple characteristics that reflect such statuses. These findings have far-reaching implications, particularly when policies are developed that reflect past/current practices in decision making or when they target particular groups. Indeed, poor women and men of color are disproportionately impacted by a myriad of policies, ranging from drugs to welfare and foster care to housing. Notably, it is not only offenders who are impacted by such policies but also victims. Furthermore, research on victims reveals that those with multiple oppressive statuses consider such policies as they determine whether to rely on the system for help.

Victims of Crime: Views from an Intersectional Lens

Sokoloff and Burgess-Proctor (2011) identify intersectionality as a key approach in the study of crime and victimization because of its ability to identify how systematized elements of inequality intersect to provide groups who are more (or less) likely to become engaged in criminal behavior or to be victimized. In this vein, scholars interested in victims of crime have begun to utilize intersectionality to expand understanding of not only who victims are but also whether programs and resources are appropriate across victims who present with different statuses.

Work on the portrayal of victims from an intersectional framework demonstrates that not all victims receive the same attention. Indeed, not only are victims with certain characteristics more (or less) likely to garner media attention, but the types of media and the portrayals of victims in the media vary according to social statuses. For example, white, middle, and upper class women who are missing or are victimized are not only more likely to be deemed newsworthy but also are less likely to be portrayed as holding responsibility for their victimization than counterparts who are poorer, lower status, and/or, are minorities (Gilchrist, 2010); those who hold multiple statuses linked to oppression are the least likely to receive any or positive media attention.

As with offending, application of an intersectionality framework to victimization is believed to enhance our understanding of victims' experiences within a social justice framework. Domestic violence, in particular, has been viewed with an intersectional lens, with the goals of improving theories, understanding justice responses, and improving services provided to victims and offenders involved in battering

relationships. While widely recognized that women are more likely than men to be injured in domestic violence incidents, less is known about how marginalized women experience domestic violence. Early intersectional research drew attention to the fact that black and white women's lives yield very different experiences with and responses to domestic violence. Sokoloff and Dupont (2005) recently reaffirmed that this framework is an important tool to utilize to enhance our understanding of the unique characteristics of intimate partner violence in marginalized communities, specifically minority, lower-class communities. Research in the past decade has further drawn on this perspective to explore the distinct experiences of other groups, such as immigrants, disabled individuals, or same-sex couples, in domestic violence experiences.

Using this framework, researchers have elucidated how women's responses to domestic violence are impacted by the multiple statuses that they hold, concluding that the statuses held by victims yield different reactions or different groups of victims may have different reasons far behind similar responses to such events (Josephson, 2002). For example, assumptions are made that black women who are victimized by black men are discouraged from reporting black men to police in domestic violence incidents, and that, as a result, they are less likely to report when they are assaulted in these communities or by their partners. Moreover, it is posited that these victims may fear that they will lose custody of their children if they report abuse. This is particularly the case when these victims reside in communities that are segregated not only racially but also by class (Cramer and Plummer, 2009). Findings, however, are mixed; some evidence supports these assumptions and other studies indicate that poor minority women are more, not less, likely to seek prosecution of their abusers (see discussion in Josephson, 2002). More research clearly is needed to further identify commonalities and differences across domestic violence victims.

Immigrant status adds an additional layer, particularly for those who are in the country illegally; these women are isolated not only within their communities but also from services available to broader categories of those who experience domestic violence. Erez et al. (2008) report that these victims also are threatened by their abusers with their immigration status, further reducing the likelihood that they will report assault incidents to police. Domestic violence within same-sex relationships also has been reviewed using an intersectional lens, with researchers noting that societal level homophobia impacts how the justice system responds to abuse within such couples; moreover, individuals in these relationships may be less likely to report or seek services because of their fears about how society views them (Sokoloff and Dupont, 2005).

Studies examining how system officials and service providers respond to victims of domestic violence reinforce the need for intersectional framing. For some time, concerns have been raised that services for victims of interpersonal violence were developed with a goal of responding to 'average' victims, but that the 'average' victim is conceptualized from a white majority framework. Josephson (2002) asserts that this has resulted in programs and services that do not recognize the experiences of not only minority women, but more importantly, women who present with a complex array of linked issues, including minority status, poverty, and residence in communities without resources or strong social networks. She argues that provision of services is hampered by the context of the multiple marginalizations that such women experience.

For example, many already utilize social services and therefore have developed relationships with government agencies associated with such services. Hence, they have formulated opinions about government agencies in general and may be less likely to seek out assistance when they are victimized because of prior negative experiences with agency personnel. In addition, because women in marginalized communities have less social capital and resources to draw on, they recognize that they are potentially more at risk when they seek assistance.

Moreover, frequently agencies in marginalized communities focus on addressing a single issue and as a result fail to recognize and address the myriad of factors that impact those who have multiple layers of oppression that need to be addressed in order to provide an adequate response to victimization. For example, groups aimed at addressing racism or poverty may fail to recognize or address compounding factors generated for those who experience DV or other victimizations (Sokoloff and Dupont, 2005; Josephson, 2002). This is further hampered by policies that, developed with an eye to one issue, ultimately constrain victims from making decisions that would help them leave abusive situations. Josephson (2002) points specifically to the requirements of AFDC/TANF that affect payments and potentially even contacts with abusers in order to ensure establishment of paternity and/or child support payments as potentially harmful to victims who desire to leave or reduce contact with abusers.

Finally, intersectionality likewise points to the need to explore resources available for individuals who do not fit into even these categories. Cramer and Plummer (2009) call attention to the fact that women who are disabled are quite isolated, frequently relying on their abuser for mobility; moreover, abuse of such individuals may not be physically violent but instead involve threats to or withholding of medicine or treatments. These victims, as well as elderly victims, are underexplored within the criminological literature and it is a lens of intersectionality that is bringing attention to them as generally unrecognized and underserved.

Conclusion

In sum, utilizing intersectionality as a lens to review traditional criminological theories, as well as to examine crime policies and justice practices, has begun to highlight populations that have to date been underexplored. While critics of intersectionality frequently raise concerns that use of this framework runs the risk of deconstruction, researchers studying crime have effectively employed intersectionality to raise awareness of how individuals who hold multiple oppressive statuses are further victimized, not only as victims of crime but even as offenders in a system that is underprepared in its identification of sources of criminality and responses to victims and offenders. As intersectionality work continues to evolve in the study of crime, we can anticipate that additional populations who are underserved will be identified, greater consideration of contradicting policies and programs will occur, and resources will be better utilized to reduce crime propensity and serve victims. Furthermore, it is

likely that such research will also clarify how experiencing these complex identities impacts not only offending or victimization but also how these two sides of criminal events share experiences within some shared settings. The intersectional lens holds significant promise for future research in the study of crime.

Abstract

This article describes the historical development of interviewing in the social sciences. It begins by noting the transition toward the end of the nineteenth century from the interviewing of informants about the lives of other people toward the elicitation of direct accounts from individuals themselves. The history of survey interviewing in the modern sense is traced from the 1920s to the period just after World War II, and from the 1950s to the present day. The emergence of less structured styles of interviewing in the early part of the twentieth century is described. Attention is directed to the variety of critical approaches to traditional conceptions of interview that became important from the 1960s onward. Briefly discussed are changes in the work roles of interviewers, the interviewing of 'special populations,' and shifts in the social acceptability of the interview itself. Finally, the implications for the interview of recent developments in new communication technologies are outlined.

Introduction

As the oral historian Paul Thompson (2000) has shown, the direct elicitation of information through question and answer has a long and venerable history. The word 'interview' seems to have originated in the sixteenth century to describe a meeting of two people of equal rank and status to discuss a matter of some importance to them. In the later part of the nineteenth century, the practice of interviewing prominent individuals in order to obtain from them an authoritative view concerning some pressing topic of the day became a common practice in journalism (Schudson, 1994). Slightly later on, the term began to take on something more like its modern sense of a device for eliciting information about some aspect of people's lives. It was not, however, until the early decades of the twentieth century that interviewing began to be seen in a methodologically self-conscious way by social scientists interested in respondents' activities, circumstances, and subjective states. By the middle of the twentieth century, the interview – in its various guises – had some claim to have become a central, indeed one might say dominant, research method in the social sciences.

The Historiography of the Interview

No detailed full-length monographic history of the interview exists, although Jennifer Platt has provided a concise, and characteristically incisive, overview of the topic (2001). The early attempt by Riesman and Benney (1956) to sketch the history of interviewing must now be considered speculative. The development of interview practice in the social sciences has been characterized by many (often unattributed) borrowings and cross-fertilizations between anthropology, political science, psychology, consumer research, social work, and sociology. Moreover, although the history of social science interviewing is treated here largely in isolation, it cannot strictly speaking be divorced from related developments such as the emergence of sampling methods, or shifts in recording technologies (Lee, 2004). It should also be noted that, as Platt (2001) points out, the methods current at a particular time often now have to be recovered from prescriptive or programmatic accounts, those used for training, for example, which might present a partial or idealized view of actual practice.

Nowadays, interviews come in many different forms. They can be highly structured with standardized questions or loosely organized around a set of topics. They can be conducted face to face, by telephone, or online. While interviews are usually conducted with single individuals, they can also be used with small groups. The diversity of interview forms, the extent of variation in interview practice, and the theoretical and methodological traffic between and within disciplines all combine to make it difficult to produce a simple linear narrative of how the social science interview developed over time. It is convenient, however, to begin with the history of survey interviewing.

The History of the Survey Interview I

During the nineteenth century, concerns arose in a number of countries about the social conditions faced particularly by the urban poor and the means by which those conditions might be ameliorated. Shaped by such concerns, a variety of groups and individuals began to undertake social investigations to identify the nature and magnitude of social problems and to provide a basis for action (Bulmer et al., 1991). Often referred to as 'surveys' but distinct from the modern conception of the term, investigations of this kind relied on the systematic collection of information about families and households usually by means of an exhaustive enumeration of local areas. Although there were those like Henry Mayhew in England, Wilhelm Riehl in Germany, and Frédéric Le Play in France, Belgium, and elsewhere who interviewed workers, peasants, and others directly, and who were not unaware of the methodological issues involved in doing so, for the most part nineteenth century, social investigators tended to use officials or functionaries as proxy informants about social conditions rather than interviewing respondents directly. Mutual distrust and suspicion between the classes, underlying conceptions of social pathology, and practical problems of access encouraged researchers to devalue direct accounts

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03222-0

from respondents in favor of indirect methods for gathering information (Marsh, 1985).

Marsh (1985: pp. 214–216) points to a number of factors that, in England at least, encouraged the transition from respondent to informant interviewing. These include the use of directly employed field-workers rather than volunteers, improvements to working hours and employment conditions that increased accessibility to working class respondents, a shift away from pathologizing discourses that blamed the poor for their own misfortunes, and a growing interest in the subjective sphere of beliefs, attitudes, and values. That parallel shifts occurred in other countries is suggested by Sklar's (1991) account of Florence Kelley's work at the Hull House in Chicago, and Lazarsfeld and Obserschall's (1965) discussion of Max Weber's involvement in a succession of empirical research projects in Germany. Bulmer et al. (1991) note that in Britain the reformist social survey had largely run its course by 1914 and the onset of World War I. The tradition remained strong in the United States through the 1920s before eventually falling victim to the Great Depression (Converse, 1987). Economic austerity reduced the foundation funding, which was an important source of support for local surveys. Research on social conditions began increasingly to be conducted under state or federal auspices, and with an enhanced role for academic social scientists who brought with them newer ideas about sampling and measurement techniques. What Converse (1987: p. 39) calls the 'new attention to measurement' encouraged the collection of individual-level data, although the emphasis remained on behavioral rather than subjective measures. Together with the increased understanding and acceptability of probability sampling, the outlines of the modern sample survey began to emerge.

The growth of newspaper advertising, radio listening, and a desire by businesses, faced with shrinking profit margins as the economic climate worsened, to understand consumer attitudes and behavior all contributed to the development of a burgeoning market research industry in the United States in the 1920s and the 1930s (Converse, 1987). The exploration of consumer attitudes soon expanded to cover wider social and political issues, a trend buoyed by pollsters' successful prediction of the 1936 US Presidential election in contrast to the failure of the magazine *Literary Digest* to predict the election result with a huge but fatally unrepresentative mail-in ballot of its subscribers.

As the interpenetrated worlds of market research and opinion polling expanded, debates began to emerge on topics such as sampling, questionnaire design, question wording, and the role of interviewers. Disagreement – partly shaped by differences between academic and polling practice – existed about the extent to which the interview should be flexible or conversational in tone or follow a more tightly structured format based on standardized questions (Converse, 1987: pp. 95–98; pp. 137–138). The amount of freedom interviewers had to interpret questions and record responses could depend on quite specific matters such as the perceived sensitivity of particular questions, but practice also reflected institutional culture and organizational history. Those bodies that gave interviewers latitude in how they conducted the interview tended, by and large, to have smaller field forces, to recruit well-educated interviewers, and to provide them with detailed training. Different interviewing styles placed different demands on interviewers. These in turn had implications for data quality – including the possibility of interviewer malpractice – interview recruitment, training, and payment. The possible role of 'interviewer effects,' the extent to which the status or demeanor of the interviewer might affect the responses obtained in the interview, was a particular concern. Converse suggests that pollsters retained relatively cordial links with sociologists and political scientists through the 1930s and into the 1940s. Disagreements with social psychologists remained, however, and intensified when the advent of war brought with it increased competition for funds, prestige, and institutional advantage.

By the 1930s, governments in many countries had begun to regard morale as an important element in the planning and prosecution of war. In the United States, when war came, a number of government agencies were set up to study military and civilian morale. Many leading figures from the world of survey research – Cantril, Lazarsfeld, Likert, Stouffer, and others – contributed to this effort. The exigencies of wartime work left little space for methodological development. What did emerge out of the wartime experience was a degree of institutional crystallization in the postwar period that increasingly saw survey research located within university-affiliated, externally funded research centers and institutes. Bodies such as the Bureau of Applied Social Research at Columbia, the National Opinion Research Center at Chicago, and the Survey Research Center at Michigan all pursued work on methodological issues, which was funded by research contracts focused on substantive topics usually of an applied nature. The extent to which experimental variations in interview practice could be built into survey designs equipped researchers with a powerful tool for studying their own methods. In the later part of the 1940s and the early 1950s, researchers at the National Opinion Research Center (NORC) conducted a series of experiments that overturned much of the conventional wisdom of the time concerning sources of interviewer bias and the role of 'rapport' in the interview (Hyman, 1954), implicitly encouraging a focus on the instrumental and task-oriented elements of the interviewer's role.

After the war, research on the use of surveys increased in a number of social science disciplines. This shift was particularly marked in sociology, but can also be seen in economics and political science, if rather less so in social psychology (Presser, 1984). Except for economics, as Presser shows, this general trend reflects the growing importance American social scientists placed on self-report measures of attitudes, beliefs, values, and other subjective phenomena. As the survey became dominant, attention turned to topics such as sampling, scaling, and questionnaire design (Platt, 2001). Discussion of survey-oriented topics such as interviewer effects and the selection, training, and supervision of interviewers also became noticeable at this time.

Unstructured Interviewing

Known early on as the 'personal' interview or 'verbatim' interview; later as the 'depth,' 'in-depth,' or 'intensive' interview; and thereafter as the 'unstructured' or 'semistructured' interview, an open, exploratory style of interviewing has often been seen as

an alternative to the more heavily standardized survey interview. In sociology, interviewing of this kind has often been associated with the work of the Chicago tradition. Initially, however, the interview was somewhat disfavored by Chicago sociologists, who preferred instead the written life history and 'undesigned materials' (Thomas, 1912), letters, diaries, memoirs, and the like. Sociologists in this period did use information from interviews conducted by social workers (Platt, 1996). Given that social work was regarded at the time as a feminized, somewhat low-status activity, it is possible that direct use of the method by sociologists was somewhat inhibited as a result. When Chicago-trained sociologists did interview, they tended to base their understanding of the procedure on literary genres derived from the life history. In consequence, they often relied on rather mechanistic strategies for invoking responses from the interviewee rather than focusing on the interactional dynamics of the interview (Lee, 2008). Ironically, it was social workers rather than sociologists who produced in the 1920s a relatively comprehensive and sophisticated approach to interviewing heavily informed by contemporary progressivist assumptions about the value of professional expertise and social scientific knowledge. This work, now largely forgotten, explored in a relatively systematic way issues related to interview dynamics, the functions of interviews, the role of the interviewer, and methods for recording and analysis (see, e.g., Queen, 1928).

In the interwar period, Carl Rogers, partly influenced by the Freudian Otto Rank, drew on his experience of working in child guidance to develop what he described as a 'nondirective' approach to counseling. Applied to research interviewing, nondirective interviewing allowed the respondent, rather than the interviewer, to assign significance to the topics covered and used a variety of strategies to signal a nonjudgmental understanding of the respondent's thinking, and the need as the interview proceeded for further elaboration or self-reflection. A similar style of interviewing emerged out of the Hawthorne studies, based this time on principles derived from the Australian psychologist Elton Mayo's reinterpretation of Jean Piaget's work (Lee, 2011).

Nondirective interviewing became widely used in the social sciences. The Hawthorne studies were central to the newly burgeoning field of human relations, and to related fields like consumer research, and organizational studies. In the late 1930s, the social psychologist Rensis Likert, who directed the Division of Program Surveys, a research unit in the US Department of Agriculture strongly oriented to the use of an open, conversational style of interviewing, invited Rogers to train the division's interviewers in nondirective methods, thus helping to widen the visibility of the method. In time, though, the popularity of nondirective interviewing waned. The method drew criticism from those who saw it as overly bland or who felt that interviewers should be free to home in on topics of specific interest, or to probe silence on the part of the respondent more aggressively. In sociology in particular, as the force of these criticisms began to be felt, attention shifted, it can be argued, toward other methods, such as participant observation, at the expense of interviewing methods (Lee, 2011).

Soon after the United States entered the war in 1941, the sociologist Robert Merton became involved in a study in which groups of soldiers were interviewed about the effects of an enemy propaganda film that they had just watched. 'Focused interviewing' (Merton and Kendall, 1946), the method that evolved out of this study, diffused soon after into marketing and consumer research. Subsequently known as the 'focus group,' the method became popular in the 1960s and the 1970s. Its relative cost-effectiveness encouraged take-up of the focus group as a method of consumer research as did, somewhat surprisingly, the invention of sales tracking technologies such as the barcode, which encouraged companies to shift from monitoring market share using unreliable recall-based surveys to a methodology that allowed exploration of the reasons behind consumer decisions (Lee, 2010). The use of focus groups subsequently diffused back into sociology and became very widely used across the social sciences in many different countries.

The History of the Survey Interview II

There have been three key postwar trends affecting interview practice in survey research: the internationalization of the survey method, the proliferation of survey modes, and the turn toward cognitive methods. The internationalization of survey research began in the late 1930s with George Gallup using franchising arrangements to set up Gallup affiliates in a number of countries. After the war, polls and surveys came into common use in many Western industrialized countries. Survey methods diffused through personal contacts and academic exchanges, the growing availability of conferences, summer schools and courses, commercial arrangements, and the encouragement of international organizations (Bulmer, 1998). Receptivity to survey-based methods depended often on cultural and political factors. For example, in France, the survey interview was not always well regarded, with some (particularly elite) social groups seeing it as a rather alien cultural form (Riesman, 1956). In the countries of the then Eastern bloc and other parts of the Communist world, survey research met with official disapproval, although this could be eased during periods of political uncertainty or change when party officials wished to monitor popular opinion. In these contexts, though, individuals could be anxious about agreeing to participate in an interview and about how to respond to politically sensitive questions (Henn, 1998).

The variety of means and media through which survey responses are elicited has expanded greatly over the years. The traditional methods of face-to-face interviewing and self-completion questionnaires were joined in the 1970s by telephone interviewing. Subsequently, a variety of computer- and Internet-mediated methods have come to the fore, and the use of mixed-mode surveys has increased (Couper, 2011). Modes differ in their implications for the role and purpose of interviewers. How these will change in the future as technologies develop remains unclear.

Beginning in the late 1970s, collaboration began to emerge between cognitive psychologists and survey researchers. In some ways, a reinvigoration of the historic links between survey research and social psychology, much of this work focused initially on question design (Jobe and Mingay, 1991) Somewhat later, something of a symbiotic relationship also developed between survey researchers and sociologists working in

the ethnomethodological tradition (see, e.g., Maynard and Schaeffer, 2000). The focus of this work – how in question–answer exchanges meaning emerges out of interaction – has obvious implications for understanding the interview.

Interviewers

If interviewing was originally a gentlemanly pursuit, by the middle of the twentieth century, survey interviewing had become a largely feminized occupation. Although historically, survey organizations differed in the extent to which they recruited by age and educational level (Converse, 1987), they retained a preference for women as interviewers, which rested on the then conventional gendered assumptions about levels of pay, household roles, and emotional labor. Research based on samples of interviewers working on the multicountry European Social Survey suggests that today, with some exceptions, men are well represented on interviewing field forces (Blom et al., 2011). Work conditions have implications for how workers perform their role, whether one sees this as 'cheating' or as an accommodative response to the demands of the job. How interviewers conceive of their role, their attitudes toward it, and the operational routines and practices they adopt have begun to be incorporated in a relatively systematic way into work on interviewer effects (see, e.g., Durrant et al., 2010). There still remains, however, a dearth of work that looks at interviewing as an occupational role, and training contexts aside (Converse and Schuman, 1974), how interviewers themselves experience their role has received relatively little attention, a reflection perhaps of their relatively low status (Peneff, 1988).

Special Populations

Interviewing, particularly survey interviewing, has tended to be directed toward members of the general population. Particular kinds of respondent – children, the powerful, members of stigmatized groups, and so on – often pose challenges that lie beyond the standard repertoire of interviewing approaches. Work in these fields has tended to produce a set of specialized literatures. Although, obviously, specific groups throw up specific issues, there are a number of key concerns that crosscut these literatures whatever the character of the group involved. Among these concerns one can note (1) the relative social positions of the interviewer and the interviewee and how these might reflect disparities of power and status, (2) the respective identities of the interviewer and the interviewee, (3) the importance of avoiding stereotypical conceptions as well as an alertness to possible unconscious assumptions, and (4) the possibility of cross-cultural misunderstandings. The (possibly problematic) role in the interview of self-disclosure by the interviewer has also been a concern with some groups.

Critical Voices

Voices were raised in the 1960s against the dominance of the interview and other self-report methods in the social sciences (see, e.g., Webb et al., 1966). More broadly, in many disciplines, radical and critical positions of various kinds emerged to challenge what was seen as a dominant orthodoxy characterized as positivistic, scientistic, and politically quiescent. In all of this the interview was not abandoned. How as a method it was to be used, however, was seen to require a fundamental rethinking of the dynamics of interviewing and a radical reconfiguration of interview practice. Some writers argued for a focus on powerful actors and institutions and advocated a robust, interrogative style of interviewing taking investigative journalism as a model (on the development of 'adversarial' research strategies, see Lee, 1993). In France, Touraine developed an approach, morphologically similar to the focus group, but embedded within politically engaged processes for social intervention and consciousness raising (Brincker and Gunderlach, 2005). More commonly, the interview was to be seen not as a more or less fleeting instrumental and extractive encounter governed by the researcher's need for information but as a shared interactional accomplishment open to the biographical, contextual, and relational underpinnings of people's lives, and in which the voice of the interviewee was to be afforded clear and unhindered expression. In work of this kind, the communicative aspects of the interview came under detailed, indeed minute, scrutiny with the focus on how, through the course the interview, both interviewer and interviewee formulate and frame questions and responses out of their reciprocal understandings of the meanings situationally produced within the interview itself. This opened to view discursive features of the interview such as the role within it of narrative, paralinguistic communication or the grounds on which cultural misunderstandings emerge, topics usually treated as invisible in conventional treatments or relegated to the status of technical 'troubles.'

Feminist writers, in particular, produced a widely influential strand of critical writing on the interview. The aim here was to overcome the traditional invisibility of women in social research, and to explicate how gendered patterns of power, domination, and disadvantage were implicated in mainstream interviewing practice. Traditional interviewing styles with their closed questions and rigid prespecification of topics tightly framed by the researcher's interests were seen as objectifying female experience and muting women's self-expression. Instead, feminist researchers emphasized as an ethical commitment the importance of establishing nonhierarchical forms of relationship between the researcher and the researched and of giving voice to those they studied. Both these aims were seen to be met more readily by qualitative interviewing methods than by other approaches. Despite broadly shared principles and commitments, debates have emerged within feminist interviewing practice about, for example, the place of self-disclosure by the interviewer, boundaries appropriate to the interview relationship and its aftermath, and the effect on the interview of the relative social positions of the interviewer and the interviewee (Reinharz and Chase, 2001).

A decidedly marginal interest until recently, the use of 'biographical methods' – a term covering a wide range of approaches, including life history and narrative methods, biography and autobiography, and oral history methods – has blossomed in the early part of the twenty-first century. All these approaches have an emphasis on the understanding of individual lives, lived out within biographical, historical, and

social contexts. Some work in the field has been driven by an explicit commitment to interdisciplinarity (Bornat, 2008). For example, in a number of European countries, a degree of openness to psychoanalytic thinking has been a feature of research focused on the interpretive understanding of individual biographies, often in relation to policy-relevant areas like migration and health care (see, e.g., Chamberlayne et al., 2000). At the same time, a degree of compartmentalization, often based on an adherence to disciplinary allegiances, can also be seen within the field (Bornat, 2008).

The biographical turn might be seen more broadly as part of a cultural trend emerging after World War II in which 'testimony' and 'witnessing' were seen to have positive value. This trend, Thomson (2007) suggests, emerged in part because the recounting of suffering, indignity, and loss provided a way for victims to respond individually and collectively to the violent traumas and upheavals of the twentieth century. Witnessing came to be regarded, too, as providing a means by which those silenced by dominant social and cultural arrangements could seek repair and redress. Since that silencing is seen to inhere in the assumptions and practices associated with dominant research traditions within Western colonialism and imperialism, an important development has been the emergence of 'indigenous methodologies' (Smith, 2012). This notion emphasizes the necessity for research to advance the needs, aspirations, and cultural integrity of colonized peoples, as defined and articulated by those peoples themselves. Typically, quantitative methods have been rejected in favor of qualitative or participative approaches, but even here, conventional methods such as interviewing have been rethought, for example, by aligning information gathering to indigenous discursive practices such as storytelling or deliberative discussion (see, e.g., Bishop, 2012).

In recent years, a rather sophisticated view of the interview has emerged from writers interested in recasting the method in the light of postmodernism. Postmodernist treatments of the interview draw on and build upon existing critiques of interview practice found in feminism, discourse analysis, sociolinguistics, and the like, but go beyond them in various ways. There has been a degree of interest, for example, in blurring the conventional boundaries between genres, with interview transcripts becoming vehicles for representational experiment through the use of poetry or performance art. Writers have also experimented with 'autoethnography,' an approach that involves a highly collaborative interviewing style with considerable attention paid to the emotions evoked for the interviewer and interviewee by the interview process itself (for a summary, see Fontana, 2001).

The Social Acceptability of the Interview

It is difficult to disentangle popular attitudes to the interview as a social encounter between the interviewer and the interviewee from wider public understandings of polling, sampling, and social science research in general. If the interview could seem, particularly to the middle classes, like an intrusion or an imposition in the 1920s, it came to be regarded in subsequent decades with varying degrees of curiosity, acceptance, or resistance (Igo, 2008). Survey participation seems to have peaked in the 1960s and researchers have fretted about declining response rates ever since. What component of this decline is due to changing cultural understandings of the interview, as opposed to other factors, is difficult to assess. There are signs, too, that more qualitatively oriented approaches have sometimes faced resistance from disadvantaged, marginalized, and exploited groups. While this clearly prompted a reorientation of interview practice across a number of fields, it might also have encouraged a shift in research focus toward groups amenable to the interview as a method (Manning, 2006). The decline in survey response rates has encouraged research on why people participate in survey interviews (see, e.g., Groves and Couper, 2012). However, there remains comparatively little work on participation in research using qualitative interviews or on how those who do participate regard the experience of being interviewed. This issue has relevance particularly in countries that require prior ethical review of research projects. Review boards often consider intensive interviews on 'sensitive' topics to be ethically problematic (Buckle et al., 2010). The emergent character of such interviews can be seen as complicating the process of obtaining informed consent, especially so where research participants are regarded as being 'vulnerable' in some way. Furthermore, the possibility that interviews might cause emotional distress to interviewees has also been a concern. As well as describing strategies that researchers can use to address such concerns, Buckle et al. (2010) point to evidence suggesting that, in fact, research interviews, even on difficult and emotionally charged topics, are often regarded positively by interviewees.

Conclusion

Atkinson and Silverman have spoken of the extent to which people today live within an 'interview society.' In such a society, the self becomes 'a proper object of narration' (1997: p. 315). Everyone is seen as having discernible views, understandings, and feelings about their own experiences. It is assumed, on the one hand, that individuals can articulate these views, understandings, and feelings, and, on the other, that it is reasonable for information about them to be elicited through direct questioning. In consequence, the interview has become ubiquitous as a method for obtaining personal information especially within professional–client relationships, while the interview also provides the mass media with a vehicle for blurring of the boundaries between public and private. In this context, it is tempting to see the interview remaining both as a pervasive aspect of life in modern societies and as a central tool of social research. One might also suppose that the methodological future of interviewing as a method resides in incremental technical change and/or innovation that remains local to particular specialisms or disciplines. The major challenge to this scenario lies, of course, in the potential impact on interview practice of the revolution in new communication technologies.

The development of the interview has always been entwined with technological change. Originally, researchers had relied on reconstructing interviews from memory, unobtrusively jotted notes, or the use of standard or private shorthands to record interviews. In some contexts, the use of stenographers was common (Lee, 2004). Carl Rogers pioneered the phonographic

recording of unstructured interviews during the 1940s. After World War II, the availability of relatively portable magnetic recorders encouraged the use of audio recording in field settings. Technological developments, such as transistorization and miniaturization (and much more recently digital recording), have allowed improvements both in audio quality and the portability of recording devices to the extent that the recording of unstructured interviews became ubiquitous in the social sciences (Lee, 2004). Although detailed case studies of adoption are rare, and the pace of technologically induced change has not always been uniform (Schober and Conrad, 2008), the development of the survey interview has also plainly been shaped, directly and indirectly, by the various affordances inherent in data processing technologies, including Hollerith machines, mainframe computers, and statistical software packages, and data acquisition technologies such as the telephone and, more recently, portable digital devices.

New communication technologies pose questions about how the dynamics of the interview itself might change in technologically mediated contexts. Advances in video-based technology raise, for example, the question of what it means to talk of 'rapport' when the respondent is virtually, but not physically, copresent (Fielding, 2010). How might the long-standing preference for standardized interview questions on surveys be modified by automated systems that use intelligent, agent-driven, interviewing techniques (Schober and Conrad, 2008)? As Schober and Conrad point out, these and other questions challenge researchers to find ways of harnessing the possibilities produced by new communication technologies without allowing those possibilities to impose themselves on the interview process in unwelcome ways. Beyond this, contemporary shifts in the use of social media, the growing ubiquity of geotagged information, the development of data fusion techniques, and the availability of large-scale commercially generated data sets all potentially have implications for the place of the interview itself within the repertoire of social research (for a provocative view of what these implications might be, see, e.g., Savage and Burrows, 2007). The interview is unlikely to disappear as a basic method in the social sciences. It is highly likely, however, that its nature, scope, use, and relationship to other methods will be radically transformed in the years to come.

Intimate Partner Abuse, Applied Research on

Jordana N Navarro, Cookeville, Tennessee Technological University, TN, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Although recognition of intimate partner abuse (IPA) did not begin until the 1970s, the gravity of the social problem is undisputed. In contrast to other fields, studying family violence has always had an implicit applied component, because research is often conducted to improve prevention and treatment programs. As a result of this applied focus, programs have evolved from an emphasis on the individual to recognition of systemic factors of abuse. This article reviews applied research on IPA that has contributed to the development of evidence-based programs combatting the problem.

Introduction

Research continues to indicate that intimate partner abuse (IPA) is a serious *global* social problem (Bacchus et al., 2010; Gadomski et al., 2001; García-Moreno et al., 2005; Gover et al., 2003; Rolling and Brosi, 2010). (This article focuses exclusively on research addressing IPA. The term 'intimate partner abuse' is used in recognition of the fact that batterers use a variety of tactics to maintain power and coercive control on victim/survivors. However, when referring to the research field in general the term 'family violence' is used.) Approximately 25% of women have experienced IPA at some point in their lifetime (Saltzman and Houry, 2009). (The debate regarding gender symmetry in IPA is ongoing and outside the scope of this article. Thus, for the purposes of this article, information will focus on male-to-female perpetrated IPA unless specifically stated otherwise.) In contrast to men, women are at greater risk of being beaten, killed, raped, or stalked by an intimate partner compared to an unknown person (Mahoney et al., 2001; Tjaden and Thoennes, 2000). As research into IPA has grown throughout the years, the definition of 'abuse' has broadened beyond physical, emotional, and sexual abuse (El-Mouelhy, 2004; Nicolaidis and Paranjape, 2009; Saltzman and Houry, 2009) to include cyberstalking (U.S. Department of Justice, 2001) and economic abuse (Corso, 2009). These advancements in the understanding of IPA have subsequently led to stronger prevention and intervention programs.

In contrast to other fields of study, research on family violence has always had an inherent applied mandate as scholars typically search for knowledge to contribute to prevention and intervention efforts combatting IPA (Gelles, 1985). The goal of these efforts is to promote evidence-based violence prevention and intervention practices. In this article, the current state of knowledge – stemming from applied research on IPA – will be reviewed. In addition, important terminology, guiding theoretical frameworks, and future research directions are discussed. To begin, a review of the definitional differences between the terms 'prevention' and 'intervention' is warranted.

Definitions

Although the terms 'prevention' and 'intervention' are often used interchangeably by laypersons, the fundamental difference between the two is important to discuss. According to Hamby (1998), prevention programs are designed to prevent violence and typically are classified into three main categories: primary, secondary, and tertiary prevention. Primary prevention programs are designed to prevent abuse before onset (Andrews, 1994; Hamby, 1998; Navarro, 2013; Smithey and Straus, 2004). In order to be successful, primary prevention programs typically attempt to foster a concurrent change in environment and increase education (Andrews, 1994; Smithey and Straus, 2004).

Secondary prevention, in contrast to primary prevention, are efforts targeted at a specific group of individuals at risk to experience the problem (Hamby, 1998). However, primary and secondary preventions are similar in that both are designed to prevent violence before onset (Hamby, 1998). Finally, tertiary prevention is very similar to intervention: services are targeted at those already experiencing the problem with the goal of preventing subsequent occurrences (Hamby, 1998). Although some programs fall neatly within one category, the lines between these programs are not impermeable (Hamby, 1998). In addition to understanding the various types of prevention and intervention models, it is equally important to understand the theoretical perspectives that often drive program development.

Theoretical Perspectives

Scholars have advocated that effective programs are those grounded in scientific theories of how problems develop and persist (Harvey et al., 2007). Utilizing theoretical perspectives in the development of prevention and intervention programs not only provides a framework for effectively planning and efficiently delivering services to target populations, but also assists scholars conducting program evaluations to discern impact. Although several theories are applicable in the development of prevention and intervention programs (see Smithey and Straus, 2004), this article will focus on two of the most widely used perspectives: the socioecological framework and deterrence theory.

According to Andrews (1994), a substantial amount of family violence prevention and intervention programs are 'person-centered' or focused on the victim/survivor or perpetrator. However, as research has called attention to the structural factors leading to IPA, the utilization of multidimensional perspectives has increased. One of the most widely referenced multidimensional frameworks utilized in the development of

prevention programs – including programs developed by the Centers for Disease Control and Prevention (CDC) and the World Health Organization (WHO) – is Bronfenbrenner's (1979) socioecological perspective.

As Bronfenbrenner (1979) theorized, individuals are constantly acted upon and shaped by their surrounding environments, which is comprised of the microsystem (e.g., the individual), the mesosystem (e.g., the family), the exosystem (e.g., the community), and the macrosystem (e.g., larger culture). Since its conception, the socioecological perspective has been utilized to guide prevention programming combatting IPA both within the United States (Navarro, 2013) and internationally (Chan et al., 2009). Typically, programs guided by the socioecological perspective engage in some variation of the following activities: (1) at the individual level, programs may target the effects of witnessing marital violence and stimulant use; (2) at the family level, programs may target male dominance and economic dependence on men; (3) at the community level, programs may target increasing the social support in the surrounding community; and (4) at the societal level, programs may target changing cultural norms that support marital violence (Harvey et al., 2007; Heise, 1998; Mitchell and Vanya, 2009).

As illustrated, the socioecological framework is especially useful, because it considers the interplay among personal, situational, and sociocultural factors (Heise, 1998). As a result, the socioecological perspective incorporates the tenets of several theoretical frameworks into one holistic model. For example, by acknowledging the importance of witnessing marital violence in the understanding of IPA perpetration, the socioecological model incorporates tenets from social learning theory. Moreover, by acknowledging the importance of cultural norms supportive of male privilege in the understanding of IPA perpetration, the socioecological model incorporates tenets from patriarchal theory. Thus, the socioecological framework draws on the strengths of many perspectives to provide a broad understanding of IPA. Aside from this framework, another widely used theoretical perspective – which also serves as the backbone of the criminal justice system – is deterrence theory.

The premise of deterrence theory can be traced back to Durkheim, who assumed that the negative consequences of punishment curbed individuals from engaging in criminal behavior – especially in instances where punishment was certain, swift, and severe (Sherman and Berk, 1984; Pogarsky, 2009). The first type of deterrence, referred to as specific deterrence, describes the process of an offender avoiding engagement in subsequent illegal activities (e.g., IPA) due to the perceived costs of such behaviors (Smithey and Straus, 2004). Because the population experiencing this includes offenders, or those experiencing the problem, programs developed using the tenets of specific deterrence are most akin to tertiary prevention and intervention. In contrast, general deterrence describes the process in which individuals (in general) abstain from engaging in crime (e.g., IPA) in order to avoid receiving sanctions (Smithey and Straus, 2004). Because the population experiencing this includes the entire community, general deterrence is most akin to primary prevention. Perhaps the most famous study applying the ideas of deterrence theory to the prevention and intervention of IPA is the Minneapolis arrest field experiment (Maxwell et al., 2002; Sherman and Berk, 1984) discussed in the following section.

Current State of Knowledge

As interest in family violence has grown throughout the years, scholars have highlighted the multiple causes of IPA – each of which provides the opportunity for prevention and intervention (Smithey and Straus, 2004). This section reviews the current state of knowledge regarding the many advancements in prevention and intervention that have occurred throughout the years, which have been empirically supported through applied research. In order to structure this section, information is organized by target populations if initiatives focused on a specific group. Following that review, the last section notes findings from comprehensive initiatives that include many components usually targeting whole communities.

Abusers

Perhaps the most famous study evaluating an intervention designed to reduce IPA is the 1984 Minneapolis arrest experiment (Sherman and Berk, 1984). In this seminal work, Sherman and Berk (1984) evaluated the impact of three law enforcement responses on batterers' recidivism (e.g., arrest, informal counseling, and ordering the batterer to vacate the premises for 8 h). At the conclusion of their study, data indicated that arrested offenders recidivated less than offenders ordered to leave the premises (Sherman and Berk, 1984). As a result, sweeping reforms occurred that led to mandatory arrest policies, despite that other scholars encountered considerable difficulty in replicating these results or replicated studies produced contradictory findings (Maxwell et al., 2002).

Acknowledging these discrepancies, Maxwell et al. (2002) recently synthesized data generated through various replication attempts in order to readdress whether arrest acted as a specific deterrent for IPA offenders. In their study, Maxwell et al. (2002) found a consistent reduction in offenders' subsequent violence following arrest. As a result of these data, the scholars noted the original findings of the Minneapolis arrest experiment were supported despite concerns from other scholars that mandatory arrest may not always be in the best interest of the victim/survivor. Aside from the debate regarding mandatory arrest, another area of inconsistent research is the impact of batterer intervention programs (BIPs).

According to Hamilton et al. (2013), three types of BIP models dominate today: the cognitive-behavioral, the psychodynamic, and the profeminist treatment (i.e., the Duluth model). Although BIP curriculum slightly varies, all focus on the behavior of the abuser and encouraging the batterer to accept responsibility for that behavior (Gondolf, 2011). Moreover, BIPs tend to focus on promoting healthy relationships, while also addressing underlying beliefs that relate to IPA (Gondolf, 2011). Unfortunately, while the aforementioned objectives are promising, only a handful of evaluations have been conducted on these programs to date – all of which indicate there is little to no lasting effect in curbing subsequent IPA (Babcock et al., 2004; Gondolf, 2011). In recognition of

this lack of impact, Gondolf (2011) evaluated several proposed ideas of how to improve these programs (e.g., treat attachment issues associated with battering, diversifying programs to account for different batterer types, including culturally sensitive material, etc.). However, after reviewing available evidence – including program evaluations – Gondolf (2011) notes there was little evidence to support these alternatives. As a result, an effective intervention program that successfully reduces the likelihood of subsequent violence remains an elusive goal.

Businesses

Since the mid-1990s, family violence scholars have increasingly drawn attention to the important role businesses have in the prevention and intervention of IPA (Murray and Powell, 2008; Urban and Bennett, 1999). The role of businesses in preventing IPA, or intervening when confronted with signs of IPA in workplace, is vital for a few reasons. First (and most importantly), victim/survivors spend considerable time at work; as a result, problems occurring at home are brought into the workplace. For example, according to a CDC report (2003), costs stemming from IPA exceeded $5 billion in the United States, which includes approximately $1.8 billion in the indirect costs of lost productivity. Second, aside from the monetary costs, an estimated 13 000 acts of violence occur in workplaces within the United States each year (Bachman, 1994) obviously placing victim/survivors at risk as well as fellow employees. Similar consequences have been documented internationally. For example, Henderson (cited in Murray and Powell, 2008) notes businesses in Australia lose more than $1.5 billion annually as a result of IPA. Due to these consequences, many businesses have now recognized their role in the prevention and intervention of IPA, including large employers such as Polaroid, Liz Claiborne Inc., and Marshalls, Inc. (Isaac, 1997).

The three main types of IPA prevention and intervention models utilized in workplaces include employer-led programs, brokerage partnerships, and union-based initiatives – many of which have undergone formative evaluations (Clarke, 1999 cited in Murray and Powell, 2008). In employer-led programs, IPA is addressed by incorporating an awareness of the problem into existing human resources structures and organizational processes (Murray and Powell, 2008). The aforementioned includes training fellow employees and managers about the dynamics of abuse in order to increase awareness of, and sensitivity to, signs of IPA in the workplace (Murray and Powell, 2008). In brokerage partnerships, employers partner with IPA social service agencies and these organizations engage in activities to raise awareness and promote understanding within the workplace (Murray and Powell, 2008). Finally, in union-based initiatives, group leaders organize to promote positive change for workers; for example, developing IPA resources to assist in prevention efforts (Murray and Powell, 2008).

According to Urban and Bennett (1999), although the goals of employees and employers sometimes differ, both groups share the common objective of preventing and reducing IPA in the workplace. In recognition of this common goal, Urban and Bennett (1999) guided the development, implementation, and evaluation of the Domestic Abuse Program (DAP) (not the actual name of the program (see Urban and Bennett, 1999)). Implemented in a plant in a rural area of Tennessee, initial program evaluation findings of DAP indicate trainings provided as part of the initiative were successful (Urban and Bennett, 1999). There were statistically significant differences among DAP trainees in three out of seven IPA concepts from pretest to a year after training (Urban and Bennett, 1999). In addition, there was a marked decrease in the projected utilization of negative and controlling behaviors among trainees following DAP (Urban and Bennett, 1999). As a result of these initial findings, Urban and Bennett (1999) note that DAP created an environment in which victim/survivors could be supported by their colleagues.

Although the aforementioned describes and illustrates the types of prevention and intervention programs currently utilized in the workplace, more work is necessary as scholars have found that employers sometimes react to IPA by punishing victim/survivors with poor evaluations or engaging in other tactics to justify their terminations (Park, 2003). These negative reactions are unfortunate, because research has found that promoting an open and supportive work environment benefits employees and employers alike. For example, Swanberg and Logan (2005) found that when employees experiencing IPA disclosed abuse to supportive employers, both benefitted. Employed victim/survivors were grateful, became increasingly loyal, and demonstrated increased motivation to excel in their duties (Swanberg and Logan, 2005).

Despite the noted advancements, a dearth of information exists on program evaluations of IPA prevention and intervention initiatives within the workplace (Urban and Bennett, 1999). Moreover, if information about workplace prevention and intervention strategies do exist, documents discussing these initiatives are rarely made available (Murray and Powell, 2008). As a result, scholars should endeavor to address this gap in knowledge moving forward by emphasizing the important benefits of program evaluations – chief of which is to ensure that initiatives were implemented properly (Murray and Powell, 2008). However, the advancements that have been made thus far further underscore the point that IPA is not a private matter between individuals, but rather a social problem necessitating the involvement of multiple levels of society – including communities.

Communities

In order to successfully combat IPA, community mobilization must occur (Harvey et al., 2007). Involving communities in prevention and intervention programs is important as these efforts can stop IPA by increasing awareness and education among residents regarding the complexities of abuse (Smithey and Straus, 2004). In addition, engaging communities in the prevention and intervention of IPA is critical as these environments can assist families throughout the lifespan and, as a result, reduce related social problems: exploitation, neglect, and violence (Andrews, 1994). While community involvement is essential to the prevention and intervention of IPA, it is particularly important in rural communities where increased isolation and limited services further complicate the problem (Gadomski et al., 2001).

According to Gadomski et al. (2001), there is minimal information on whether public education campaigns increase

awareness of IPA or promote changes in attitudes and behaviors regarding abuse – particularly among rural communities. To address this gap in knowledge, the scholars conducted a 7-month campaign and utilized the following: mailings to libraries and clergy, posters, printed advertisements and media articles, and radio advertisements (Gadomski et al., 2001). At the conclusion of the campaign, Gadomski et al. (2001) found statistically significant increases in favorable behavioral intention (e.g., assisting the victim, consulting with others about IPA) among residents of the targeted community – particularly among men. Similar public information and awareness campaigns have also been utilized internationally.

Although Harvey et al. (2007) note that initiatives based solely on public awareness campaigns cannot typically foster *sustained* change, these programs can be successful in reaching large numbers of people. For example, the United Nations' (UN) Interagency Campaign to End Violence Against Women consisted of a regional mass media campaign held in Africa, Asia, Latin America and the Caribbean, and the Pacific (Harvey et al., 2007). The types of media utilized by the UN to increase awareness of IPA included the following: badges, community events, public service announcements, posters, theme songs, and T-shirts (Harvey et al., 2007). Based on the outcomes of the campaign, the initiative appeared to be successful at fostering change at a macrolevel in several countries: legislative reviews were conducted, new laws were implemented, and funding was allocated to IPA agencies (Harvey et al., 2007). Although programs may utilize public awareness and education campaigns to reach specific audiences, other initiatives – particularly found in the international community – engage community residents directly in the effort to combat IPA.

One example of such an initiative exists in Ecuador, where close friends and relatives (referred to as compardres) are partnered with newlywed couples for a period of time in order to assist in instances of marital conflict (Smithey and Straus, 2004). A similar program exists in Marshall Islanders of Oceania, where elders supervise and intervene in episodes of IPA (Counts et al., 1992 cited in Smithey and Straus, 2004). In other programs, not only did community members become directly engaged with combatting IPA (through attending educational trainings), but passed this knowledge on by training fellow residents as well (Kugel et al., 2009). As a result, the *Familias con Voz* (Families with a Voice) prevention program provides a sustainable method to combat IPA – especially among migrant communities (Kugel et al., 2009). Indeed, utilizing community leaders as 'promoters' (referred to as *promotoras*) of change has achieved great success in other fields (e.g., health services), and is now recognized as a viable method to address blatant inequities (Ingram et al., 2008). Overall, researchers have found that community-based approaches are most successful when residents take ownership of the issue as well as participate in program efforts to address the problem, which includes engaging youth as well (Harvey et al., 2007).

Educational Institutions

School-based education programs are vital components of prevention and intervention, because targeted youth learn nonviolent conflict resolution and interpersonal skills necessary to stop the cycle of violence (Smithey and Straus, 2004). Indeed, recognizing that research has supported the relationship between exposure to violence and a higher likelihood of engagement in IPA – the involvement of youth in prevention and intervention programs is important (Harvey et al., 2007). The aforementioned is also particularly critical, because evaluation research has largely shown that youth are less accepting of IPA after exposure to prevention and intervention programming (Jaffe et al., 1992). In reviewing the various forms of school-based IPA prevention and intervention, scholars have identified four different levels of programming, which become more involved and detailed as children grow (Powell et al., 1996).

The first and most commonly used level entails programming directed at students, such as teaching sessions (Powell et al., 1996). The second level typically involves parents and peers in the program in order to reinforce nonviolent messages inside the classroom through peer groups and outside the classroom through parents (Powell et al., 1996). The third level of prevention requires working with social groups, such as neighborhoods, to promote nonviolent behaviors inside school and in the surrounding community (Powell et al., 1996). Finally, the fourth level of prevention targets economic opportunities, firearm availability, media exposure, and similar policy/legislative matters in order to promote broader social change that addresses violence in general (Powell et al., 1996). Aside from the level utilized, it is also important to consider the age of the target population in program development and implementation as effects are greatest when the activities are age appropriate (Harvey et al., 2007).

Prekindergarten (Pre-K) and elementary school programs typically include fostering a general understanding of interpersonal abuse rather than focusing on specific types of violence (Allen, 2009; O'Brien, 2001). The rationale for generalizing the topic is that children within these age groups are not old enough to fully understand the complexities of IPA; however, they still need strategies of how to react when confronted with violence (Allen, 2009; O'Brien, 2001). Fortunately, research has identified several evidenced-based practices utilized in early violence programs: bibliotherapy, group discussions, games, and role playing (Jaffe et al., 1986 cited in Thompson and Trice-Black, 2012). Although many early programs focus on older children (e.g., elementary school and older) evidence suggests Pre-K youth can also benefit from prevention activities (Allen, 2009). For example, evidence indicates that the Creating a New Generation of Peacemakers (hereafter Peacemakers) program successfully impacted Pre-K children (Allen, 2009).

During a 5-week period, the Peacemakers program promoted conflict avoidance tactics, conflict resolution skills, and encouraged respect for others among Pre-K children (Allen, 2009). In order to accomplish the aforementioned, five one hour interactive educational sessions were hosted over a 5 week period, which consisted of various activities: designing a square for a Peacemakers quilt, creating a puppet to illustrate feelings, drawing a safe place in the home or neighborhood (Allen, 2009). At the conclusion of the program, youth involved in the Peacemakers initiative demonstrated statistically significant improvements in desirable skills: conflict avoidance, conflict resolution, and respect for others (assessed by collecting

evaluations of children from teachers) (Allen, 2009). In addition to Peacemakers, several other similarly focused early programs have been successful at reducing the impact of violence on young children: Childreach; Second Step: A Violence Prevention Curriculum; Resolving Conflict Creatively Program; PeaceBuildiers; and The Incredible Years (Guttman et al., 2006). In contrast to young children, programs targeting middle and high school youth are normally more direct.

Programs targeted at middle school and high school youth are more detailed and usually target dating behavior (O'Brien, 2001). Moreover, by the time youth reach high school age, programs typically comprise of multiple components: an integrated curricula, peer groups, and violence-awareness events (O'Brien, 2001). One example of a school-based dating violence prevention program targeting older youth (13–15 years of age) is the Safe Dates program in North Carolina (Harvey et al., 2007). In the Safe Dates program, youth attended 10 educational sessions as well as participated in a poster contest and theater production (Harvey et al., 2007). At the conclusion, youth involved in the program reported less engagement in negative behaviors: psychological, moderate physical, and sexual dating violence perpetration (Harvey et al., 2007). Moreover, there were statistically significant declines in moderate physical victimization (Harvey et al., 2007). Aside from targeting youth at particular grade levels, initiatives have also been developed for student organizations (e.g., student athletes) within schools.

According to Miller et al. (2012), the Coaching Boys into Men (CBIM) program utilizes the relationship between male high school student athletes and male coaches to promote positive development among youth. In the CBIM program, coaches serve as positive role models who lead student athletes in weekly discussions about respect and dating violence prevention (Miller et al., 2012). In order to lead discussions, coaches themselves undergo a 60-min training session led by a violence prevention advocate at which they are introduced to a Coaches Kit to help them facilitate the program (Miller et al., 2012). In total, the program encompasses three main components: (1) raising awareness of negative behavior and encouraging positive alternatives, (2) promoting gender equality and respect, and (3) developing bystander intervention skills through the modeling of coaches (Miller et al., 2012).

Results indicate the CBIM is an effective school athletics-based program to reduce dating violence (Miller et al., 2012). According to Miller et al. (2012), CBIM athletes reported greater intentions to intervene and more positive bystander behavior. Similarly, the Mentors in Violence Prevention (MVP) program is another effective method to engage student athletes and leaders in order to raise awareness of IPA, challenge norms supportive of violence, and promote bystander intervention (Harvey et al., 2007). Results from the MVP initiative indicate trainees improved on knowledge and attitudes of IPA following the program (Harvey et al., 2007). Overall, school-based violence prevention and intervention initiatives are essential to reducing IPA and dating violence, but more evaluation is necessary to understand long-term impacts of these efforts (Harvey et al., 2007; O'Brien, 2001). Another target population that is critical to combatting IPA involves those individuals interacting with victim/survivors on a daily basis – first responders and the general medical community.

First Responders and Medical Personnel

As knowledge of IPA has grown, the importance of first responders and medical personnel as 'first lines of defense' in the effort to combat abuse has also increased. For example, according to Smithey and Straus (2004), information about IPA is now part of medical school curricula and research is routinely funded to study the problem. Additionally, the American Medical Association suggests all providers screen for IPA, a practice that was subsequently endorsed by other professional organizations: American College of Emergency Physicians and the American College of Obstetricians and Gynecologists (Alpert, 2007). Finally, the Joint Commission on the Accreditation of Healthcare Organizations mandates hospitals have IPA screening and referral protocols in place to assist victim/survivors (Alpert, 2007). The importance of first responders and medical personnel cannot be understated as these individuals are also usually the first individuals to interact with victim/survivors in rural communities where there is limited access to other social services – thereby further emphasizing the significance of their role in the prevention and intervention of IPA (Elliott, 1993 cited in Hyman et al., 2000).

The convergence of victim/survivors and first responders/medical personnel provides important prevention and intervention opportunities. Scholars have found approximately 17% of IPA victim/survivors seeking emergency care disclose abuse to personnel (Larkin and Parks, 2009). However, despite this knowledge, research indicates a majority of medical personnel do not query patients about IPA during consultations (Rodríguez et al., 2001). This lack of questioning is likely due to several disclosure barriers found within the medical setting: patients' belief that clinicians lack the time to discuss abuse, patients' fear of involving law enforcement, patients' perceptions that medical personnel lack interest in discussing IPA, and patients' concerns about confidentiality (Rodríguez et al., 2001). In recognition of the aforementioned barriers, programs have focused on engaging various personnel to increase intervention within the medical setting. For example, after attending training on IPA, medical students reported greater comfort with responding to signs of abuse (Moskovic et al., 2008). Research conducted on programs with a similar focus produced comparable outcomes: medical students reported greater awareness and understanding of IPA (Wielichowski et al., 1999 cited in Davidson et al., 2001; Jonassen et al., 1999). In addition to medical students, efforts are targeted at practitioners directly.

In a review of programs targeted at health care providers, Davidson et al. (2001) note that relatively few published studies have assessed long-term impacts among practitioners. However, one study evaluated the impact of the RADAR (Routine screening, Ask direct questions, Document your findings, Assess patient safety, Review patient options and referrals (Harwell et al., 1998)) program on health care providers located within various community health centers (Harwell et al., 1998). Per Alpert (2007), the RADAR program has been utilized extensively in various health care settings since 1992 and is especially suited to encouraging intervention among medical personnel. Composed of three parts, the RADAR program includes (1) training to all health care staff, (2) theoretical context to understand impacts of abuse on

various parties involved, and (3) follow-up support to health care staff (Harwell et al., 1998).

According to Harwell et al. (1998), after phase one of the RADAR program was completed, trainees reported greater comfort and knowledge regarding IPA. Moreover, most trainees expressed satisfaction with the training component of RADAR, and that the training met their expectations as far as information presented (Harwell et al., 1998). Although some of these immediate impacts of the training declined by 3 months and there was little improvement in personnel actually documenting abuse, Harwell et al. (1998) note the training was effective in providing the necessary knowledge to providers in order to assist IPA victim/survivors in the medical setting. While victim/survivors typically seek out first responders and medical personnel to help 'physically' heal them, many seek out religious leaders to assist in 'spiritual' healing. Therefore, religious leaders are critically important to prevention and intervention efforts.

Religious Leaders

Research indicates that victim/survivors of IPA often turn to religious leaders after victimization to obtain guidance and acquire context for understanding abuse (Fortune, 2001; Strickland et al., 1998). Hence, religious leaders can have a pivotal role in the prevention and intervention of IPA, which can either be a positive or negative experience for the victim/survivor (Fortune, 2001; Strickland et al., 1998). Unfortunately, in cases of the latter, research has documented victim/survivors experiencing the following: abandonment by their faith communities, 'shaming' and blaming for *their* abuse, and otherwise being held responsible for their own victimization (Fortune, 2001). As a result, engagement of religious leaders in the prevention and intervention of IPA is especially important.

In one noteworthy study, Jones and Fowler (2009) describe the implementation and evaluation of a Faith Leader Training Program, designed to train religious leaders about how to recognize and respond appropriately to IPA. Developed as a six hour training module, the basic components included providing information regarding: an overview of IPA, effective and appropriate responses to abuse, unique challenges faced by faith leaders (e.g., misinterpretation of sacred texts), and local IPA services for victim/survivor referral (Jones and Fowler, 2009). In addition, a quarterly newspaper was mailed to all program participants that kept the topic visible (Jones and Fowler, 2009). According to Jones and Fowler (2009), pre- and posttraining surveys indicate statistically significant changes in trainees' attitudes, beliefs, and knowledge of IPA as well as issues concerning victim/survivor safety. Finally, aside from training results, other indications suggest that these efforts had a substantial impact. For example, a church involved in the program developed a spiritual spa for victim/survivors residing at a local women's shelter (Jones and Fowler, 2009).

Putting It All Together: Coordinated Community Action Models

The Coordinated Community Action Model (CCAM) developed initially from the work of advocates in the 1980s who were combatting IPA from a holistic perspective (Barner and Carney, 2011; Hamby, 1998; Pence and Paymar, 1993; Shepard et al., 2002). Referred to as the Duluth Domestic Abuse Intervention Project (DAIP or (later) the Duluth model), the following nine agencies collaborated to develop standard policies and procedures for responding to IPA: the county court, the county jail, three mental health agencies, the police department, the probation department, the prosecutor's office, and the shelter (Pence and Paymar, 1993). Overall, the seminal work of Pence and Paymar (1993) was critically important to the family violence field for several reasons: (1) DAIP shifted focus away from victim/survivor responses to emphasizing punitive responses to abusers' violent episodes, (2) DAIP shifted focus away from individual-level factors to recognition of violence rooted in patriarchy, and (3) DAIP established the important role of collaboration in intervening and preventing IPA. Throughout the progression of the family violence field, CCAM like DAIP have continued to be utilized as methods of prevention and intervention of IPA (Barner and Carney, 2011; Hamby, 1998; Navarro, 2013; Shepard et al., 2002) including internationally (Chan et al., 2009). Moreover, although relatively few evaluations exist on CCAM, Hamby (1998) reports several available evaluations have produced positive results indicating the viability of these programs.

Although CCAM vary in scope, most models include a collaboration with counselors, judges, police, probation officers, prosecutors, and shelter advocates (Shepard et al., 2002). Through this collaboration, most CCAM continue the traditional focus of Duluth's DAIP: emphasize offender accountability (e.g., pro-arrest or mandatory arrest policies) and supportive victim/survivors (Shepard et al., 2002). (It is important to acknowledge the ongoing debate regarding whether mandatory arrest policies are always in the best interest of victim/survivors.) In one noteworthy CCAM evaluation, Shepard et al. (2002) reviewed whether enhancements made to the existing DAIP model impacted offender recidivism. DAIP enhancements, referred to as EDAIP, included the use of danger assessment tools, a probation-sentencing matrix, and a computerized monitoring system (Shepard et al., 2002).

Although there were several challenges encountered during the course of the evaluation, Shepard et al. (2002) note their data show EDAIP offenders had lower rates of recidivism compared to those in DAIP. As a result, while Shepard et al. (2002) state that their study was unable to evaluate the effectiveness of any one component, they claim their data suggest that risk of recidivism can be reduced with enhanced coordinated responses. According to Chan et al. (2009), although CCAM were originally implemented more along the lines of community justice approaches, the concept of coordinating community responses to social problems has shown merit in prevention as well.

Program evaluation findings from a CCAM utilized in a small community in Orlando, Florida, support the claims made by Chan et al. (2009). In contrast to the previous study noted, this CCAM (referred to as Project Courage) focused on the primary prevention of IPA by engaging several stakeholders within the target population: businesses, community residents, educators and youth, first responders, and religious leaders (Navarro, 2013). In addition to involving multiple groups in the prevention effort, Project Courage included multiple activities as part of the overall initiative: a training to empower individuals to 'Recognize, Respond, and Refer' (R3) for IPA,

a business initiative referred to as 'Purple Key,' multiple youth programs, and religious leader roundtables (Navarro, 2013). Although there were several challenges encountered during the implementation and progression of the program, results from the first year of the initiative indicate that Project Courage was successful at fostering an immediate change in the recognition and response to IPA. Thus, evidence suggests CCAM continue to be a novel and effective approach to the prevention and intervention of IPA.

Methodological Limitations and Future Directions

This article provided an overview of the current state of knowledge regarding evidence-based IPA prevention and intervention efforts – stemming from applied research on the topic. While the aforementioned studies highlight the important advancements made after four decades of effort, there are several limitations that should be noted. First, many of the studies noted in this article were limited in their ability to assess long-term impact. As a result, additional research assessing long-term impacts (e.g., >1 year) is warranted before firm conclusions are drawn.

Second, despite the important role that certain individuals have in the prevention and intervention of IPA (e.g., religious leaders and employers), there was a lack of information regarding initiatives targeting these groups specifically. Thus, there was limited applied research to report. Moreover, few studies focused on marginalized populations or special populations (e.g., military). For example, in one cutting-edge study, Dichter and Marcus (2013) note relatively little is known about the prevalence of IPA among female veterans. As a result, future research should endeavor to address these persistent gaps in knowledge.

Third, applied research often presents unique challenges to scholars, which may impact the desired rigor of studies. While scholars attempt to overcome these challenges and utilize the most rigorous methods (e.g., randomized designs, comparison groups, sufficient follow-up, replication, etc.; Whitaker et al., 2013), this is not always possible. As a result, the quality of studies presented in this article is not consistent. This lack of consistency is well recognized in the literature, and several scholars have discussed the challenges and barriers faced in applied research (see Navarro, 2013; Riger, 2002; Whetstone and Tewksbury, 2000). Taking all the aforementioned into account, this article should serve as a starting point to conduct a more in-depth review of the applied research presented here.

Abstract

Sexual and intimate relationships are often plagued with violent acts. This article focuses on two key challenges that researchers, as well as groups and organizations seeking to provide support, face in interpreting and understanding peoples' real experiences of violence within their relationships and the consequences that these interpretations have for understanding and providing support to victims. The first challenge revolves around distinguishing between different types of intimate partner violence, as categorized by Michael P. Johnson (1995, 2008). The second challenge considers the role that gender, sexual orientation, race, and ethnicity play in the interpretations and explanations for intimate partner violence.

Sexual and intimate relationships are often plagued with violent acts. Data from the National Intimate Partner and Sexual Violence Survey show that more than one in three women (35.6%) and one in four men (28.5%) in the United States report rape, physical violence, and/or stalking by an intimate partner in their lifetime (Black et al., 2011). These experiences of violence within their relationships impact the individual's life in a variety of ways, such as post-traumatic stress disorder, injury recovery, sexually transmitted diseases, long-term anxiety and stress, depression, emotional detachment, sleep disturbances, suicidal behavior, missed work or school, homelessness, substance abuse, and more (Aguilar and Nightengale, 1994; Breiding et al., 2008; Crofford, 2007; Heise and Moreno, 2002; Johnson and Leone, 2005).

Given the prevalence of violence within intimate relationships, much research, including those studies listed above, details the patterns of violent behavior in intimate relationships and builds an understanding of how and why such violence occurs (for overviews, see Hattery, 2009; Johnson and Ferraro, 2000). This article focuses on two key challenges that researchers, as well as groups and organizations seeking to provide support, face in interpreting and understanding people's real experiences of violence within their relationships and the consequences that these interpretations have for understanding and providing support to victims. The first challenge revolves around distinguishing between different types of intimate partner violence, as categorized by Michael P. Johnson (1995, 2008). The second challenge considers the role that gender, sexual orientation, race, and ethnicity play in the interpretations and explanations for intimate partner violence.

Johnson's Categories of Intimate Partner Violence

Early sociological research on intimate partner violence generally followed two perspectives: the family-violence perspective, attributed originally to Gelles (1974) and Strauss (1979); and the feminist perspective, exemplified by Dobash and Dobash (1979), Walker (1984), and Kurz (1989). The two perspectives utilized different types of data and came to very different conclusions about the prevalence and causes of intimate partner violence. The family-violence perspective relies primarily on large-scale quantitative data analysis and concentrates on discrete, violent acts occurring during family conflict. Studies using this perspective perceive violence as a relatively common element of intimate and family relationships, which can be exacerbated by stress. In contrast, scholars working within the feminist perspective are more likely to use qualitative data, such as interviews of women living in battered women's shelters. The feminist perspective views intimate partner violence as a consequence of patriarchal relations, constructions of gender roles, and structural constraints that limit exit opportunities for women experiencing intense, systematic beatings (Buntin et al., 2004).

The differences in conceptualizing violence in relationships, and the reliance on quite different sources of data resulted in very different conclusions about the prevalence and nature of intimate partner violence from these two perspectives. The findings have been so different that researchers from both perspectives have long argued that the other perspective misunderstands the nature of family violence (Johnson, 1995). Scholars in the family-violence paradigm see violence as a natural, relatively common, and sometimes mild aspect of intimate relationships, whereas feminist researchers perceive violence in intimate relationships as more intense, more brutal, and the result of male attempts to physically and psychologically control women.

Michael P. Johnson (1995, 2008), however, argues that rather than one perspective being wrong and the other right, what really creates the confusion and conflict between the family-violence perspective and the feminist perspective is a homogeneous conceptualization of intimate partner violence. In his groundbreaking analysis, Johnson (1995) argues that both perspectives are accurate, and that they are simply examining different phenomena. He originally distinguishes between two types of intimate partner violence: patriarchal terrorism and common couple violence. Due to the large-scale survey sources utilized, the family-violence perspective primarily observes 'common couple violence' or violence that is generally more moderate in nature, rarely escalating to extreme levels, and more gender balanced, i.e., both men and women participate in the violence at similar rates (Johnson, 1995). In other words, this is the 'everyday' sort of violence that occurs within approximately half of intimate relationships (Olson, 2002). In contrast, the

feminist perspective's dependence on case studies from battered women's shelters yields data on 'patriarchal terrorism,' the more intense, extreme cases of violence in which the male partner physically and psychologically controls and abuses his female partner. This form of violence and control is deeply embedded in "patriarchal traditions of men's right to control 'their' women…a form of terroristic control of wives by their husbands that involved the systematic use of not only violence, but economic subordination, threats, isolation, and other control tactics" (Johnson, 1995: 284). This form of violence is less frequent; therefore it shows up less in large-scale survey data. However, its higher level of intensity means that the consequences for the victims and their children are more extreme, thus leading some women to seek help at battered women's shelters where they come to the attention of the researchers working from the feminist perspective.

Johnson's differentiation between different types of violence helped make sense of the conflicting findings within the intimate partner violence literature. He has since revised and developed his framework, testing it on additional data (Johnson, 2001, 2008; Johnson and Leone, 2005). Other scholars have also tested his typology on different data sets and found support for this approach to domestic violence (Graham-Kevan and Archer, 2003; Leone et al., 2004; Olson, 2002). Johnson's revised typology (2008) includes four categories of intimate partner violence rather than two: intimate terrorism, violent resistance, situational couple violence, and mutual violent resistance. The first, intimate terrorism, is what Johnson previously referred to as patriarchal terrorism. It is violence committed with the intent to gain general control over one's partner. This is the violence that has been the focus of feminist scholars and activists for decades. It is also the type of violence that receives the most media attention and is generally what most people mean when they think of 'domestic violence.' Not all violence perpetrated against intimate partners can be categorized as such. In addition to 'situational couple violence,' Johnson's revised term for the common couple violence, in which there is violence without the intent to fully control the partner, his more recent framework also includes two more categories. 'Violent resistance' refers to the violence perpetrated by partners, generally women, who are the victims of intimate terrorism. In this category, the violence erupts as a way to resist or escape the violence and control of the intimate terrorist. This category includes legally defined self-defense, but also acts of violence that would not be considered self-defense in a courtroom, but stem from the desperation of an individual who has been terrorized and isolated for extended periods. Finally, Johnson defines a much smaller category of intimate partner violence, that of 'mutual violent control' (Johnson, 2008). In these cases, both partners engage in violence and controlling behaviors against each other. In other words, the violence is an active battle for control and domination within the relationship (Johnson, 2008).

Johnson's differentiation of intimate partner violence and the subsequent theoretical development and empirical testing by him and other intimate partner violence researchers has added significantly to our understanding of the role of violence within intimate relationships, as well as the diverse psychological, social, and even economic consequences it can have for the participants and their families.

The Influence of Gender, Sexual Orientation, and Race/Ethnicity on Understandings of Intimate Partner Violence

Gender

Not surprisingly, intimate partner violence is interpreted quite differently by the public and by help providers as a consequence of the race, class, gender, and sexual orientation of the couple. Johnson's work, discussed above, highlights the role that gender plays in shaping understandings of what constitutes intimate partner violence, as well as the likelihood of an individual to experience it. In Johnson's (1995) earlier conceptualization, patriarchal terrorism, the gendered nature of the category is more apparent. Even translated to intimate terrorism, however, research shows that this combination of violence and control-seeking behaviors is primarily perpetrated by men against women (Graham-Kevan and Archer, 2003; Johnson, 2001). Situational couple violence, in contrast, is more gender balanced (Johnson, 1995, 2008).

When it comes to seeking help from organizations and institutions providing assistance to victims of intimate partner violence, the feminist perspective leads us to expect that victims of intimate partner violence are female, potentially making it difficult for male victims to seek help and find assistance. In addition, the expected gendered nature of intimate partner violence may obscure situational couple violence and result in fewer resources for couples for whom the violence is not part of a systematic attempt by the male partner to control the female partner. For these couples, seeking assistance from an institution that perceives all intimate partner violence as intimate terrorism perpetrated by men on women will be useless at best.

In addition, qualitative data collected in four Chicago neighborhoods suggest that race, class, and sexual orientation can also create a miscommunication between victims and help providers. The Chicago Health and Social Life Survey (CHSLS) (Laumann et al., 2004) included qualitative interviews with community leaders and service providers within these neighborhoods that vary by race, ethnicity, and sexual orientation. These data provide a window into the ways that these social characteristics may shape the understandings of violence by the help providers, as well as the likelihood that victims will seek their assistance and the information that the victims may feel comfortable sharing.

Sexual Orientation

Intimate partner violence within same-sex relationships has only recently begun to receive research and media attention. The assumption that domestic violence is primarily perpetrated by men against women meant that it was perceived as a phenomenon found almost exclusively in heterosexual relationships. Chicago's 'Shoreland' neighborhood (a pseudonym) is home to a significant portion of the city's gay community.

> Annie, a leader in the gay and lesbian community in Shoreland, describes intimate partner violence as 'a huge issues in the queer community. Most women don't believe it, though, so it is hard to bring pressure.' She is concerned about the lack of services available to gay and lesbian victims of domestic violence. She feels that homophobia in women's shelters prevents lesbians from seeking and receiving help there. She also points out that there are no places for male victims to go at all.
>
> Buntin et al., 2004: 250–251

Interviews with police officers in the neighborhood illustrate confusion and discomfort regarding same-sex intimate partner violence. Same-sex domestic violence calls were perceived as more violent than heterosexual calls, and therefore more dangerous to the officers. In addition, the common assumption that intimate partner violence is violence perpetrated by men on their female partners creates confusion when officers are confronted with same-sex partners. They can no longer depend on this mental framework in trying to discern the perpetrator from the victim. "A male officer in Shoreland described gay domestic violence calls as disorienting and unsettling…" (Buntin et al., 2004: 251). In general, the officers also appeared to offer little in the way of referrals to service organizations, perhaps also as a result of the uncertainty of where to send gay and lesbian victims of intimate partner violence for assistance.

Although more research is being done in this area, the literature on intimate partner violence within same-sex relationships is still limited. Adam M. Messinger (2011) finds that victims with a history of same-sex relationships are more likely to experience verbal, controlling, physical, and sexual intimate partner violence, even from opposite sex partners. Other researchers have also begun to explore the role that violence plays in same-sex relationships (see, for example, Cruz and Firestone, 1998; Halpern et al., 2004; Merrill and Wolfe, 2000; Renzetti, 1992).

Race/Ethnicity

In the two Latino neighborhoods profiled in the CHSLS, cultural explanations of intimate partner violence were common among service providers. Many perceived Mexican or Puerto Rican culture as the source of intimate partner violence in these neighborhoods, focusing on cultural concepts of male machismo and female subservience. One Catholic church worker stated that "domestic violence is so much a part of the culture that people lack a vocabulary to identify it" (Buntin et al., 2004: 254).

These cultural explanations, however, serve to obscure the structural and economic factors at play as well. For example, a Catholic priest interviewed described violence as "the dark side of Mexican culture" (Buntin et al., 2004: 254). He went on, however, to describe a scenario for violence that is filled with structural and economic influences rather than Mexican culture.

> When a man comes up to the United States, he is suddenly much richer in absolute terms than he was in Mexico, but much poorer in relation to the wider population. He feels inadequate, belittled. Often he will require his wife to stay at home and not work. But even if this is not the case, the only person he can push around is his wife, or the kids when he is in his castle. So there is a very high incidence of domestic violence in Westside.
>
> Buntin et al., 2004: 254

Thus, while he perceived Mexican culture as the source of the violence, the example he gives points toward other factors, such as the migration experience, socioeconomic inequality in the US, and feelings of powerlessness in society by members of marginalized groups. Similarly, service providers interpret Latinas' refusal to leave a violent situation in terms of the cultural value of familia or family. While they may be accurate in part, these cultural explanations are blind to the powerful role that can be played by economic dependence on the perpetrator, lack of family support in the area, and perhaps fear of seeking assistance because of undocumented immigrant status.

In the African-American neighborhood referred to as Southtown, a different type of explanation for intimate partner violence dominated. While service providers in the Latino neighborhoods perceived that their clients willingly accepted violence in their relationships for cultural reasons, providers and community leaders in Southtown often refused to recognize that intimate partner violence was a significant problem in their neighborhood at all. Since the CHSLS data show rates of intimate partner violence in Southtown that are higher than any of the other neighborhoods, such statements suggest a denial or ignorance of an important aspect of residents' family life. The lack of recognition of intimate partner violence in the neighborhood likely stems from a lack of willingness by residents to seek help from service providers in the neighborhood (Buntin et al., 2004). CHSLS researchers also perceived a lack of willingness on the part of the African-American community to fully participate in research conducted by outside organizations. "Although the data are limited, there does seem to be a clear pattern – especially among those affiliated with religious organizations – of violence being interpreted primarily in terms of 'moral choice' and only secondarily in terms of such structural and economic factors as poverty, racism, and lack of education" (Buntin et al., 2004: 259). These moral perspectives may serve to discourage people from seeking help in Southtown. It is also unclear how an organization emphasizing moral choice can intervene effectively except by continuing to preach the virtues of moral strength. Within the context of a structural reality of little economic opportunity, financial instability, racism, etc., individuals may be less inclined to seek assistance from organizations focusing on a moral approach.

These findings from the Chicago neighborhoods included in the CHSLS (Laumann et al., 2004) suggest that gender, sexual orientation, race, and ethnicity play a crucial role in shaping opportunities for assistance available to victims of intimate partner violence. Gendered, cultural, and religious beliefs on the part of the service providers can limit their ability to effectively provide assistance to victims in their

neighborhoods. The findings of the CHSLS suggest that more emphasis on structural and economic factors may improve the ability of service providers to positively impact the lives and circumstances of families dealing with intimate partner violence. For example, service providers working with immigrant victims of domestic violence could gain insight into their clients' experiences and choices by increasing their understanding of immigration policy and the social process of migration. For example, a woman whose legal status in the United States is dependent on her relationship with her husband may feel that she must accept abuse from him rather than risk her legal status. Her acceptance of abuse, in this case, stems not from a cultural belief about women's roles in the family, but on her political and economic position within the US. Consequently, assisting her escape from this situation requires different tactics on the part of the organization.

Similarly, to effectively address violence within African-American and gay/lesbian neighborhoods, those individuals and organizations seeking to assist victims of domestic violence must recognize the ways that cultural understandings about domestic violence (i.e., that 'it doesn't happen in our church' or the implicit expectation that victims are female and perpetrators are male) serve to mask the very real instances of violence and abuse found in predominantly African-American or same-sex neighborhoods.

Abstract

Many individuals suffering from epilepsy are refractory to medical management. Uncontrolled seizures are psychologically and socially disruptive. Brain surgery affords many individuals the opportunity to lead normal lives by dramatically reducing, or eliminating seizure activity. Surgery, however, carries the risk of postoperative cognitive decline. One way to minimize this risk is to undergo intracarotid sodium amytal testing (IAT). This article familiarizes the reader with the IAT and discusses the strengths and weaknesses of this particular approach to the presurgical examination of the epilepsy patient. Contributions of the IAT to our understanding of the neuroanatomical substrates of language will also be discussed.

Introduction

Approximately 20–40% of individuals with epilepsy do not respond adequately to treatment with anticonvulsant medications (Aicardi and Shorvon, 1997). Uncontrolled seizures are not only psychologically and socially troublesome to individuals with epilepsy, but are also economically disruptive, as many individuals with epilepsy are either underemployed or unemployed. Neurosurgical intervention affords patients with pharmacologically intractable epilepsy the opportunity to eliminate, or at least reduce seizure activity. While epilepsy surgery has become increasingly safe and effective, it is not completely without risk as structures important to both language and memory are commonly epileptogenic and are the target of neurosurgical intervention. Thus, in order to avoid significant insult to language (i.e., aphasia) or memory (i.e., amnesia) the treatment team must ascertain whether the tissue to be resected is functional, and if so, must determine the likelihood and degree of possible postoperative cognitive impairment. It is, therefore, important that both language and memory be evaluated presurgically to assess the risk of impairment postoperatively. The most widely used method for determining language dominance in potential epilepsy surgery cases is known as the intracarotid amobarbital test (IAT), a method employing selective anesthetization of brain tissue. Not only has this procedure been clinically useful, it has also led to important insights into the neuronal correlates of language – particularly our understanding of inter- and intra-hemispheric differences in language organization. This article will detail the basic elements of the IAT, the strengths and weaknesses of the procedure, and the lessons it has taught us regarding the cortical organization of language. Although the Wada test is also considered highly useful in predicting postoperative memory outcome (Milner et al., 1962; Chelune, 1995), we will restrict our focus in this article to the use of the Wada test as it applies to language functioning.

Historical Overview

Gardner (1941) was the first to apply an anesthetic directly to the brain in an attempt to identify eloquent language cortex. He injected procaine directly into the cortex of two left-handed patients who were being evaluated for neurosurgical intervention. The first patient was a 35-year-old man undergoing neurosurgical intervention to remove a tumor located in the right frontal premotor area, while the second was a 27-year-old woman with a history of left-frontal craniotomy and excision of a cerebral cyst who subsequently developed epilepsy. This second patient was to undergo a second left-frontal surgical intervention in order to excise the presumed epileptogenic tissue. Gardner understood that the patients' left-handedness increased the likelihood of having right-hemisphere language dominance. Additionally, he postulated that he might be able to do a more complete resection if language dominance was located in the hemisphere contralateral to the one being operated upon. In the case of the first patient, a trephine involving the right frontotemporal region was completed and a hypodermic needle was inserted into the underlying cortex. Twenty-seven cc of 0.75% procaine hydrochloride was then injected causing a mild left-facial droop without aphasia. The right cerebral hemisphere was subsequently removed successfully without language complications. To evaluate language dominance in the second patient, the left-facial motor area was located using electrical stimulation. A solution of 10 cc of 1.0% procaine was injected just anterior to this, without subsequent aphasia. This patient subsequently underwent a large left-frontal resection with no postoperative aphasia and marked improvement in seizure frequency.

Following Gardner, Juhn Wada, a Japanese-Canadian neurologist, published his paper outlining the IAT (Wada, 1949). Wada originally developed the IAT, known to many as the 'Wada test,' to study the spread of epileptiform discharges between the left and right halves of the brain in patients undergoing unilateral electroconvulsive therapy. Wada noted a disruption of language took place when the presumed language-dominant hemisphere was injected with amobarbital and anesthetized. Based on this observation, he reasoned that this technique may be useful in determining hemispheric language dominance in neurosurgical candidates, and thus reduce the cognitive complications following neurosurgical intervention. Working as a fellow with Theodore Rasmussen at the Montréal Neurological Institute, Wada then deployed the IAT as a part of the preoperative evaluation of persons with

medically refractory epilepsy, and in 1960 the first English publication describing the IAT appeared (Wada and Rasmussen, 1960).

Current Use of the IAT

Currently, the IAT generally has three purposes in epilepsy surgery centers. First, the IAT helps to determine the language-dominant hemisphere of those being considered for neurosurgical intervention for retractable epilepsy. Language lateralization not only helps to reduce postoperative language impairment, but can also help predict risk for postoperative memory impairment (Chelune et al., 1993). The second purpose of the IAT is to corroborate the presumed hemispheric seizure onset determined by other diagnostic methods (e.g., electroencephalography (EEG), video EEG telemetry and ictal semiology, structural and functional radiography, etc.). Finally, the IAT helps to assess the functional memory capacity of the hemisphere contralateral to the one injected (Chelune, 1995).

Although the IAT is an invasive procedure and carries a small degree of risk (e.g., stroke, embolism, etc.), it remains an integral component of the comprehensive presurgical evaluation of patients with intractable epilepsy. It is not without its detractors, however, and some have suggested the use of less invasive procedures such as functional magnetic resonance imaging (fMRI) for language localization is preferable. Others have suggested that the use of baseline neuropsychological testing in conjunction with other test results (e.g., ictal EEG and structural MRI findings) can satisfactorily predict postoperative memory decline (Stroup et al., 2003; Baxendale et al., 2006). Indeed, routine use of the IAT has declined over the last decade, even as the number of epilepsy surgeries has increased. In one survey, only 12% of centers reported that every surgical candidate underwent IAT (see **Figure 1**). By contrast, 85% of centers used the IAT on every patient in 1993 (Rausch et al., 1993). Despite criticisms and a decline in its routine use, the IAT remains the gold standard for the lateralization of language dominance. A recent world-wide survey of 92 epilepsy surgery centers from 31 countries showed that nearly half of all epilepsy surgery centers routinely utilize the IAT during presurgical workups (Baxendale et al., 2008). Furthermore, almost half of all epilepsy surgery centers in the United States conduct the IAT on 75% or more of their patients. Moreover, in the United States the capacity to perform the IAT is one of the certification criteria required of epilepsy centers under the current National Association of Epilepsy Centers (NAEC, 2001) guidelines.

Figure 1 Cerebral angiogram of the left vertebral artery showing the posterior circulation of the brain. The posterior cerebral arteries can be seen toward the middle and upper portion of the figure. These arteries are typically the target of selective Wada testing.

Rationale and Description of the IAT

The basic concept behind the use of the IAT is to determine how well one hemisphere of the brain can support essential cognitive functions such as language and memory, while the other hemisphere is anesthetized. Because the IAT anesthetizes only part of one cerebral hemisphere, it allows one to assess the cognitive functions served by each hemisphere; that is, it is assumed that disruptions of language and memory during the IAT are a consequence of the temporary 'lesioning' of the injected hemisphere, and that the IAT mimics the effects of resective surgery involving that hemisphere. Moreover, because there is a greater incidence of atypical speech development (i.e., right hemisphere or bilateral speech representation) in those with epilepsy, it is important to evaluate rather than presume language lateralization in individual patients.

Although there are other study techniques that can be used to help determine the presumed cognitive functioning of specific brain regions (e.g., fMRI, magnetoencephalogram (MEG)), the IAT is relatively unique in that it uses deactivation as opposed to activation of functional tissue to assess presumed cognitive functioning. In order to do this, the IAT makes use of an agent to anesthetize a portion of one hemisphere of the brain – typically those areas of the brain that receive their blood supply from the internal carotid artery (ICA; commonly known as the anterior circulation, which comprises the anterior cerebral artery, middle cerebral artery, and the anterior choroidal artery). The areas of the brain subserved by these vessels include the lateral frontal and temporal lobes, as well as a portion of the mesial temporal structures such as the anterior one-third of the hippocampus. Alternative selective Wada tests are increasingly used. These procedures make use of microcatheters to anesthetize more circumscribed portions of the brain such as those subserved by the posterior cerebral or anterior choroidal arteries. Potential advantages of selective Wada tests are that they allow assessment of a specific cognitive function such as memory, without disrupting other cognitive abilities such as language. This selectivity has led some to conclude that there may be fewer false positive memory test results, meaning fewer memory test failures due to aphasia rather than amnesia, compared to the more traditional IAT (Der-Jen et al., 2006). Nonetheless, many centers are reluctant to routinely perform selective studies due to possibly higher complication rates and the increased technical expertise demanded. At our center, for example, selective Wada testing

is attempted only when the results of the initial IAT are of questionable validity (e.g., because the patient was overly sedated during the procedure) or when results conflict with data from other tests.

The most widely used anesthetic agent is sodium amobarbital, which crosses the blood–brain barrier (a functional obstruction in the brain's circulatory system, which usually keeps harmful substances out of brain tissue) easily, allowing for a rapid anesthetic effect. Other agents, such as methohexital, pentobarbital, etomidate, and propofol, are also used at some centers. Although the exact methodology varies from center to center, the IAT typically begins with a cerebral angiogram. Angiography is performed with the patient lying in a supine position on a table. Access to the ICA is gained via a catheter inserted through an incision or puncture near the groin that allows access to the femoral artery. The catheter is then typically directed by a neuroradiologist or interventional neurologist until it is placed in the ICA just distal to the common carotid bifurcation contralateral to the cerebral hemisphere to be studied. Cerebral angiography is then performed to examine the amount of cross-flow from one hemisphere to another and to detect atypical vascular organizations that may lead to complications or atypical results (see Figure 2). For instance, a fetal origin to the posterior communicating artery may lead to excess amobarbital being dispersed into the posterior cerebral artery, while the presence of a fetal origin persistent trigeminal artery may lead to amobarbital being delivered to critical respiratory and cardiac centers in the brainstem – an event that could result in death.

The IAT usually begins with the patient holding his arms into the air with his palms upward and counting aloud. Although the amount of amobarbital varies by center, typically anywhere between 50 and 150 mg is injected into the catheter over the course of 4–6 s. The drug is then flushed through the catheter with saline. Immediately following the injection, the patient will often begin to display the telltale signs of neurological dysfunction associated with the anterior cerebral circulation such as contralateral hemiparesis or hemiplegia (weakness or paralysis of the limbs), dysarthria, and at times the patient's eyes will deviate ipsilaterally. If injection of the language-dominant hemisphere was undertaken, abnormalities such as speech arrest and paraphasic errors will often be observed. Speech arrest alone does not necessarily signify the disruption of speech centers within the brain as it is often seen following nondominant hemisphere injections as well, presumably due to frontal lobe dysfunction causing an akinetic mutism-like effect. Thus, speech must be assessed carefully to ensure proper identification of language dominance. Throughout the procedure the patient is monitored via EEG to assess the degree of ipsilateral slowing.

Figure 2 Cerebral angiogram via the right internal carotid artery. Notice the mild degree of cross-flow of contrast to the left anterior cerebral artery via the anterior communicating artery. This degree of cross-flow is typically not concerning as amobarbital is injected at a much slower rate than the contrast used for angiogram, thus leading to a lesser degree of cross-flow during the actual intracarotid sodium amytal testing examination.

After an assessment of basic neurological functions, the language and memory portion of the IAT is typically performed. Most centers use a combination of spoken words and objects presented to the patient while under the effects of amobarbital. At our center, the neuropsychologist performing the assessment uses a tablet computer secured to the hand via a strap to present both written words and common objects to the patient. The patient is asked to read the word or name the object in order to assess their language ability during the procedure. If the patient is unable to produce the correct response, the word is read or the object is named three times to the patient to ensure encoding. Following the presentation of stimuli, which typically takes between 2 and 3 min, the patient's language abilities are assessed. Baseline language functions typically return within 8–10 min, and afterward the patient is asked to recall test stimuli. Most often, the patient is unable to spontaneously recall many of the test stimuli, in which case the patient is presented with a recognition task and asked to select the previously learned stimuli from a set of three similar words/objects.

At many centers, including our own, a second injection is performed on the opposite hemisphere. This allows for a more accurate language assessment as it gives the examiner the opportunity to rule in or out the possibility of bilateral language representation. A second injection also allows for the assessment of functional capacity in the portion of the brain to be resected, which gives the examiners further insight into potential postoperative cognitive decline. The second internal carotid artery is typically injected anywhere between 30 min and several hours after the first injection to ensure that the effects of the amobarbital from the first injection have completely resolved. The test procedure is then repeated, typically using different, but equivalent stimuli in order to reduce difficulties interpreting test results due to practice effects.

Problems and Considerations

Although the rationale underlying the IAT seems straightforward, the performance and interpretation of the procedure are not. Both the determination of speech dominance and that of memory representation are subjective, and the protocols used in

the IAT vary, sometimes greatly, between centers. Additionally, given the invasiveness of the procedure, very little is known about how individuals absent of neurological abnormalities might perform. As a result, there is no data with which to make comparisons between those being considered for surgery and those who are neurologically normal. The following discussion examines some of the procedural difficulties as well as the complications involving the interpretation of results.

Although many centers perform the IAT, there is a great deal of argument regarding whether or not it is necessary to evaluate both cerebral hemispheres. Some centers perform only a unilateral IAT to either determine language lateralization or to assess whether or not the hemisphere contralateral to the planned surgical resection can support cognitive functioning (a concept known as functional reserve; Chelune, 1995). Wellmer et al. (2005) argue that a bilateral IAT is often redundant. In their retrospective review of 107 cases having undergone bilateral IAT, results from the unilateral IATs performed on the side of intended surgery would have accurately lateralized language in over 80% of cases. Of course that means the 20% of patients who were incorrectly classified would be at a much greater risk of postoperative language impairment following a standard resection. Loddenkemper et al. (2004) reported a case of aphasia following a left-sided hemispherectomy in a 55-year-old man with early childhood onset epilepsy as a result of a motor vehicle accident. Preoperatively the patient was assessed using unilateral IAT of only the left hemisphere. The patient was fully capable of speech and was able to follow commands during the IAT and it therefore was assumed that he was right-hemisphere language dominant. However, the patient's postoperative aphasia would argue that his language representation was bilateral, which may have been detected had he undergone a bilateral IAT (in which case he would presumably be fully able to speak and follow commands following a right hemisphere injection as well). Transient language impairment can be seen in more selective resections as well. We reported on a case in which a 46-year-old patient showed transient moderate to severe naming deficits (2 months, but not 18 months) after a right subtemporal selective amygdalohippocampectomy (Pearson and Packwood, 2012). The patient underwent a unilateral right-sided IAT in which no apparent language deficits were observed. Given the patients postoperative deficits, it was assumed the patient actually had bilateral language representation and that a bilateral IAT would have helped us understand the patient's postoperative risks more fully.

Various drug parameters, for example, amobarbital dosages, concentrations, volume of amobarbital and saline mixture, rate of delivery (steady or incremental), the use of alternative anesthetic agents, and method of delivery (hand or automated injection) also vary widely between epilepsy centers (Rausch et al., 1993). These variations in drug delivery may lead to discrepant findings that make comparison of studies difficult. Drug parameters affect the extent and duration of anesthesia. For instance, a faster rate or larger volume of injection will typically perfuse a more extensive volume of brain, thus compromising more domains of function, whereas smaller volume or slower rate injections will lead to a greater concentration of drug in a more circumscribed area of the brain, possibly leading to more intense or prolonged drug effect.

The desired level of anesthetization is a fine balance that avoids patient obtundation compromising patient test participation on the one hand, while avoiding inadequate hemisphere anesthetization on the other. Ideally, the drug should be dosed and delivered in such a way that it models as closely as possible the effects of surgery. Finally, the drug effects should be enduring enough to allow sufficient time to administer the IAT completely.

Interpretation of the IAT is predicated on the assumption that brain regions supplied by the anterior and middle cerebral arteries are inactivated during anesthesia. However, a neuroimaging study by Hart et al. (1993) suggests that this assumption is not necessarily true. Using single-photon emission computed tomography, they found that there is a great deal of interindividual variability in the regions actually perfused by amobarbital after ICA injection. Further, varying degrees of cross-flow into the contralateral hemisphere or posterior circulation is present depending on the individual vasculature of each patient, which leaves some degree of uncertainty about validity of the results obtained (Hart et al., 1993). Although these individual characteristics can be evaluated to some degree before the IAT using the cerebral angiogram, it is impossible to predict all factors that may complicate interpretation of results. Further, the correlation between contrast medium and amobarbital distribution is limited by differences in methods of injection (e.g., Rausch et al., 1993) and the physical properties of the material injected.

Procedural differences are not the only factors that complicate the interpretation IAT results. The definition of what constitutes language dominance also varies somewhat between epilepsy centers. Benbadis et al. (1998) described two popular ways of determining hemispheric dominance (often referred to as the 'laterality index') during IAT. One method compares hemispheric differences in duration of speech arrest to produce an index varying from 1 (strong left-hemisphere dominance) to −1 (strong right-hemisphere dominance). The second method uses language performance on a specific battery of language tests obtained during anesthetization of each hemisphere to produce a ratio ranging from −100 (strong right-hemisphere dominance) to 100 (strong left-hemisphere dominance). Although these two methodologies would appear to measure similar constructs, this does not seem to be the case. Indeed, in a study of 21 patients by Benbadis et al. (1998), there was no significant correlation between the laterality indices based on speech arrest and performance on a language battery. Many centers have their own 'in-house' methodologies to evaluate language. These tasks range from simple naming, repetition, and comprehension paradigms to more robust assessments that evaluate the full gamut of language abilities. Despite these differences in protocols, a multicenter study of seven epilepsy centers found a relatively high degree of interrater reliability for language lateralization using the IAT (Haut et al., 2002). Additionally, the validity of the IAT to establish hemispheric language lateralization is well established (Dodrill, 1993).

Contribution of the IAT to the Study of Language

The IAT has a number of advantages as a research tool relative to other methodologies. Compared to lesional studies, the IAT

makes it possible to obtain baseline data in the individual to be studied. Additionally, it has allowed researchers to gather large amounts of group data where the 'lesion'-to-assessment interval is relatively homogeneous and thus minimizes confounding variables related to point of recovery. The IAT also allows for the production of a fully reversible lesion, which is useful when it is necessary to study the bilateral functioning of a single subject. Despite these advantages, there are a number of disadvantages the most notable being the brevity of the drug effect, and the possibly limited generalizability of the findings. When gathering clinically relevant information is of paramount importance, there is, within the time constraints of the IAT, little opportunity to manipulate the nature of the stimuli. Furthermore, because the IAT is carried out in individuals with typically chronic cerebral dysfunction (epilepsy), it is unclear if the findings obtained pertain to normal populations, or even to groups with other neurological conditions. Nonetheless, the IAT has allowed researchers to explore not only the intra- and interhemispheric differences in language representation and their correlates, but also, by looking at individuals with brain injury, the functional resiliency and plasticity of brain structures.

Early Studies of Language Lateralization

The first large-scale studies of language using the IAT were carried out at the Montreal Neurological Institute in the mid-1960s. Branch et al. (1964) reported on 119 mostly left handed or ambidextrious patients who underwent either bilateral (97 patients) or unilateral IAT. Of the 71 left-handed individuals assessed, 34 patients (48%) were found to be left-hemisphere language dominant, 27 patients (38%) showed evidence of right-hemisphere language dominance, and 10 patients (14%) were determined to have bilateral language representation. Of the 48 right-handed individuals assessed, 43 (90%) were determined to be left-hemisphere language dominant. The remaining 5 (10%) individuals demonstrated right-hemisphere language dominance, while none of the right-handed subjects showed bilateral language representation. Also assessed was the degree to which early cerebral injury contributed to language representation. Of 27 left-handed patients with left hemisphere cerebral injury before the age of 5 years, 18 (67%) were right-hemisphere language dominant, and 3 (11%) were found to have bilateral language. Those individuals who had not sustained an early cerebral injury were much less likely to have right-hemisphere language dominance. Indeed, of these 44 subjects who had undergone IAT, 28 (64%) were found to be left-hemisphere language dominant, while 9 (20%) and 7 (16%) were found to be right-hemisphere dominant or to have bilateral language representation respectively.

Milner et al. (1966) further described the 18 subjects from the previous series with presumed bilateral language representation. Seventeen (94%) of these individuals were left handed. In six of these cases, no speech arrest was noted following either the right or left hemisphere injections. The remaining patients showed speech arrest and language impairment after both injections.

In a larger study of 371 individuals, Milner (1975) examined the issue of language lateralization and handedness even further. Of 140 right-handed individuals without any evidence of cerebral injury before the age of 5, 134 (96%) were left-hemisphere language dominant. None of these individuals showed bilateral language representation. One-hundred-and-twenty-two left-handed patients were also reported upon, of which 82 (67%) were left-hemisphere dominant, and two groups of 18 (15%) individuals were found to be right-hemisphere language dominant and to lack clear dominance respectively. Of the 78 left-handed patients who had sustained an early cerebral insult, 40 (51%) were right-hemisphere language dominant, 23 (30%) were left-hemisphere language dominant, and 15 (19%) had bilateral language representation. Much less variability was seen in the 31 right-handed individuals who had sustained an injury before the age of 5, as 25 (81%) showed left-hemisphere dominance, and 4 (13%) and 2 (6%) showed right and bilateral dominance, respectively. Thus, left handedness appears to play a role in the likelihood of atypical speech dominance following early cerebral injury.

These early studies on language lateralization provide an excellent framework for understanding language dominance; however, they are not without flaws. First, at the time of publishing, the IAT was in its infancy. Angiography was not performed on any of the patients reported. Thus, the amount of cross-flow and potentially abnormal vasculature was undetermined. Second, a portion of the subjects used in all studies underwent only unilateral injections (although a majority of subjects also underwent direct cortical stimulation and language mapping in an attempt to confirm language lateralization).

The Medical College of Georgia has one of the most comprehensive databases of patients to have undergone the IAT. Lee (2010) recently reported on the IAT results from presurgical candidates evaluated at the Medical College of Georgia and found that approximately 81% of dextral individuals were found to be left-hemisphere language dominant, while 18 and 1% were found to be mixed and right-hemisphere language dominant, respectively. With regards to left-handers, 50% showed left-hemisphere language dominance, while 42 and 8% were mixed and right-hemisphere language dominant, respectively. Although similar in many regards, this particular study shows that bilateral language representation in left hemisphere patients undergoing a presurgical workup for retractable epilepsy may be more common than previously thought.

Predictors of Atypical Language Representation

Atypical language representation has been linked to a variety of patient characteristics. As revealed by the studies of Milner and colleagues, age of injury to the left hemisphere plays an important role in language dominance. Since the resiliency of the brain is maximal during the early years of life, injury at a very early age might induce either the intact or damaged hemisphere to reorganize (i.e., accommodate speech and language zones) so as to compensate for functional losses. Intrahemispheric language reorganization has been found to be more likely than interhemispheric reorganization after 6 years of age. In an early study conducted by Rasmussen and Milner (1977) examining left-handed patients who had sustained a left cerebral hemisphere insult before 6 years of age, 49

(53%) patients displayed right cerebral language dominance and 17 (19%) patients showed evidence of bilateral language representation. Persistence of neurological deficits, most notably hemiparesis, following early brain injury also appears to increase the likelihood of atypical language dominance. Indeed, several studies have suggested that left hemisphere injuries sufficient to cause hemiparesis have been found to be associated with atypical language dominance (Ajersch and Milner, 1983; Woods et al., 1988; Rey et al., 1988).

The Crowding Hypothesis

Interhemispheric language reorganization is more likely to occur at earlier ages; however, there is some evidence that reorganization comes at a cost to cognitive abilities usually subserved by the right hemisphere. This phenomenon is often referred to as the 'crowding' effect (Teuber, 1974). Evaluation of verbal and nonverbal functions during the IAT in epileptic patients with early onset of left hemisphere dysfunction has revealed that patients with atypical (right hemisphere) speech representation perform as well as patients with left hemisphere speech on most measures of language functioning (Strauss et al., 1990). However, patients with atypical language representation often perform more poorly than left-hemisphere language-dominant patients on nonverbal tasks. Lansdell (1969) has reported lower than expected nonverbal IQ scores in individuals with right-hemisphere language dominance. Novelly and Naugle (1985) have also shown that males tend to have lower PIQ than VIQ scores in patients with right-hemisphere language dominance. Other studies have found no differences between groups of individuals with left- and right-hemisphere language dominance (Mateer and Dodrill, 1983; Rausch et al., 1991).

Patterns of Hemispheric Speech Representation

Amobarbital studies of patients with epilepsy have also challenged the notion that hemispheric language dominance falls into discrete categories. Rather, it is more likely that language representation falls on a continuum from strongly left-hemisphere dominant to strongly right-hemisphere dominant, just as handedness seems to fall on a continuum from strongly dextral to strongly sinistral. However, other data suggest that cases might not fall along all points of such a continuum. Specifically, there are four major patterns of hemispheric speech representation. Toward the left-dominant end of the spectrum, there are indeed several clusters representing degrees of left speech dominance; however, individuals with bilateral or right speech dominance tended to center at these respective points, without the gradation observed for left hemisphere representation (Kurthen et al., 1994).

Language Lateralization in Bilingual and Deaf Individuals

A limited number of amobarbital studies have addressed two other important issues, namely the intra- and interhemispheric organization of bilinguals, and the organization of sign language. With respect to studies of bilinguals, several reports have consistently shown that the interhemispheric organization of both languages is complementary (i.e., hemispheric dominance for the two languages is similar). Intrahemispheric organization, however, appears to differ by language. Gomez-Tortosa et al. (1995) report on a bilingual patient who underwent left common carotid amobarbital injection with subsequent language evaluation in both languages. Speech impairment was noted in both languages; however, following the removal of a left parasylvian arteriovenous malformation, the patient developed deficits speaking her native tongue, without any language impairment of her second language.

Because of the potential for deaf individuals to have experienced some degree of cortical reorganization, reports of IAT results in this population are of particular significance. Such studies provide tentative data about whether findings from normal-hearing individuals concerning the organization of sign language apply to deaf individuals. One such study conducted by Damasio et al. (1986) showed evidence of complete left hemisphere dominance in a right-handed individual in both signed English and finger spelling. Thus, evidence of bilateral language representation for sign language was not found.

Alternative Methodologies in the Study of Language and Future Directions

Even though the IAT continues to be the standard presurgical means of assessing lateralization of language, its invasiveness, and the degree of inherent risk involved with the procedure make alternative methodologies very attractive. Some centers have begun using less-invasive strategies such as fMRI or MEG to help determine the functional organization of language in the workup of patients with intractable epilepsy. However, the reliability and predictive value of these tools have only begun to be assessed clinically. Although data suggest a high concordance rate between these less-invasive techniques and IAT in right-handers, that does not seem to be the case with regards to mixed and left-handed individuals (Dym et al., 2011). Additionally, techniques such as fMRI require a great deal of technical expertise and dedicated time in order to make work. Despite this, it is almost a certainty that these various noninvasive strategies will begin to take the place of the IAT language assessment across major epilepsy centers around the world.

Intrinsic Motivation: A Cultural Perspective

Qian Wang, The Chinese University of Hong Kong, Hong Kong SAR, China

Abstract

Western-originated research on intrinsic motivation has well documented its implications for optimal psychological functioning, and the role of autonomy-supportive environmental factors in cultivating intrinsic motivation. There exist theoretical analyses suggesting either a culture-specific or a universal view about intrinsic motivation across cultures. This article reviews these theoretical analyses with reference to the extant empirical research on intrinsic motivation among non-Westerners. It concludes with some reflections to highlight the value of, as well as a warranted caution in, taking a cultural perspective to study intrinsic motivation.

Intrinsic motivation is defined commonly as driving forces of behavior that individuals deem inherent to the activities undertaken – namely, the activities themselves being interesting, enjoyable, and meaningful – in contrast to non-intrinsic forces in terms of incentives or pressures (e.g., rewards or deadlines) that are external to the activities. There has been much research among Westerners documenting (1) how intrinsic motivation may be related to optimal cognitive and socioemotional functioning, and (2) what factors may foster or hinder intrinsic motivation (see Deci and Ryan, 2001). This Western psychology of intrinsic motivation has been recently called into question regarding its universality (vs culture specificity), like many other areas of research in psychology (e.g., Arnett, 2008; Henrich et al., 2010). This article thus takes a cultural perspective to summarize and evaluate theoretical views and empirical evidence regarding intrinsic motivation among non-Westerners (mostly East Asians and particularly Chinese, whom the majority of the extant research concerns).

Original Research on Intrinsic Motivation in Western Cultures

As reviewed comprehensively elsewhere (e.g., Deci and Ryan, 2001; Lepper et al., 2008; Ryan and Deci, 2000; Sansone and Harackiewicz, 2000; Wigfield et al., 2006), intrinsic motivation has been found to be related to an array of optimal psychological functioning among Westerners, ranging from enhanced self-regulation, persistence, and achievement in various domains including academics, sports, and health behavior, to enhanced well-being in terms of positive emotional experience and self-esteem. It has also been evidenced among Westerners that environmental influences such as autonomy-supportive parenting or teaching may foster intrinsic motivation, whereas controlling parenting or teaching may hinder intrinsic motivation. Specifically, autonomy-supportive parents or teachers respect children's or students' sense of autonomy, and thus encourage them to freely express their thoughts and feelings and also give them opportunities to make their own decisions, whereas controlling parents or teachers allow children or students little freedom to express themselves or make decisions on their own, but pressure them to follow through with agendas and meet up standards and expectations set by parents or teachers.

Theoretical Views Regarding Intrinsic Motivation in Non-Western Cultures

How may the aforementioned findings among Westerners with respect to (1) the implications of intrinsic motivation for psychological functioning, and (2) the environmental influences that affect intrinsic motivation, may be generalized to non-Western cultures? There are theoretical views suggesting either culture specificity or universality.

Under the rubrics of individualism vs collectivism (see Oyserman et al., 2002) or independent vs interdependent orientations (see Markus and Kitayama, 1991), Western cultures (prototypically the European American culture in the United States) have been contrasted with Eastern cultures (prototypically the Chinese-originated Confucian culture in East Asia). In particular, it has been contended that the collectivistic or interdependent cultural orientation in East Asian societies such as China, Japan, and Korea prioritizes social relations over personal attributes, and hence, intrinsic motivation (which entails individuals personally finding the activities undertaken interesting, enjoyable, and meaningful) may not play a significant role in East Asians' psychological functioning (see Hau and Ho, 2010; Wigfield et al., 2006). Another theoretical analysis compares the so-called Socratic approach to learning in Western cultures and the so-called Confucian approach to learning in Eastern cultures (Tweed and Lehman, 2002). This analysis reveals a focus on pragmatic outcomes of learning (e.g., a good job, rather than intrinsic motivation for the sake of learning itself) in Eastern cultures, also suggesting the possibility that intrinsic motivation may be of less import in Eastern (vs Western) cultures.

As to the issue concerning environmental influences, it has been argued that autonomy-supportive vs controlling parenting or teaching may have different ramifications for the development of intrinsic motivation among East Asian (vs Western such as European American) children and students (see Iyengar and DeVoe, 2003; Markus and Kitayama, 2003). This argument is also based on the notion that the collectivistic or interdependent cultural orientation discussed earlier

predominates in East Asian societies. Taking controlling parenting or teaching as an example, Eastern Asian (vs Western such as European American) children or students who highly value their relationships with their parents or teachers may be more likely to find the agendas, standards, and expectations set by their parents or teachers meaningful and take them on willingly. Moreover, the so-called Confucian approach to learning requires respect and obedience to authority figures such as parents and teachers and prefers learning to be structured by authority figures rather than self-directed by children or students (Tweed and Lehman, 2002), which also suggests possibly different effects of autonomy-supportive vs controlling parenting or teaching on children's or students' intrinsic motivation in Eastern (vs Western) cultures.

Contrary to the foregoing analyses suggesting culture specificity, there are both Western-originated and indigenous Eastern views suggesting universality in how intrinsic motivation may affect psychological functioning and how environmental factors may influence intrinsic motivation. American-originated self-determination theory (SDT) makes the case that there is a basic psychological need for autonomy and satisfaction of this need promotes optimal human functioning universally (see Deci and Ryan, 2000). Intrinsic motivation is one of the conditions that satisfy the universal need for autonomy by ensuring individuals acting out of their own determination (i.e., out of personally recognized interest, enjoyableness, and meaning of the activities undertaken) and thus may be conducive to psychological functioning regardless of culture. Vice versa, satisfaction of the need for autonomy also cultivates intrinsic motivation by affording individuals the freedom to pursue activities that they personally find interesting, enjoyable, and meaningful. According to SDT, given the universality of the need for autonomy, the role of environmental influences such as autonomy-supportive parenting or teaching in satisfying this need and fostering intrinsic motivation (vs the role of environmental influences such as controlling parenting or teaching in thwarting the need for autonomy and hindering intrinsic motivation) may well be similar across cultures (see Deci and Ryan, 2001).

In analyzing indigenous Chinese notions, Lee (1996) identified intrinsic motivation of learning as an inherent element in Confucianism, which entails "learning for self-realization" (i.e., learning for the purpose to "cultivate oneself as an intelligent, creative, independent, and autonomous" human being). Of particular note is that Lee (1996) observed: "While much of the discussion on Eastern cultures points to collectivism, there is a neglect of 'individualism' or individuality in the Eastern tradition". Wang and Li (2003) echoed: "The Chinese self is often viewed as consisting of a predominant orientation toward interdependence and relatedness… it is sometimes taken to an extreme to mean that the Chinese lack a sense of individual self…" Specifically, Wang and Li (2003) highlighted individualistic goals for learning including loving/enjoying learning, and autonomous regulation of learning including a desire to be free (e.g., "I do not like anyone to watch over my schoolwork") expressed by Chinese students when probed to describe their beliefs about learning (see also Li, 2006). Taken together, these analyses suggest that the beneficial effects of intrinsic motivation on psychological functioning and the role of autonomy-supportive parenting or teaching in promoting intrinsic motivation (vs the role of controlling parenting or teaching in impeding intrinsic motivation) documented among Westerners may also be evident among non-Westerners such as Chinese.

Notably, some pioneering cross-cultural research has also hinted that intrinsic motivation as a key element of the individualistic or independent orientation is not exclusively absent in collectivistic or interdependence-oriented cultures, such that value of autonomy indeed is endorsed universally across cultures (Schwartz, 1992). Moreover, socioeconomic developments that have been happening in many societies around the world are moving traditionally collectivistic or interdependence-oriented cultures toward "increased emphasis on individual freedom-focused values" including intrinsic motivation (Inglehart and Oyserman, 2004).

Empirical Evidence Regarding Intrinsic Motivation in Non-Western Cultures

There is a relatively small body of empirical work investigating intrinsic motivation in non-Western cultures that may help to appraise the culture-specific vs universal views.

Implications of Intrinsic Motivation

Several studies utilized international data sets to examine the relations from intrinsic motivation to secondary school students' academic achievement in Western and Eastern cultures. Chiu and colleagues (Chiu and Chow, 2010; Chiu and Zeng, 2008) analyzed the data set of the Organization for Economic Cooperation and Development's Program for International Student Assessment (OECD-PISA, 2000), and showed that 15-year-old students' intrinsic motivation in reading and mathematics (e.g., "When I read/do mathematics, I sometimes get totally absorbed.") was positively associated with their actual performance in reading and mathematics in 41 countries around the world including Western societies such as the United States of America, the United Kingdom, Germany, and France, and Eastern societies such as Hong Kong, Indonesia, Korea, and Thailand. Zhu and Leung (2011) analyzed the data set of the Trends in International Mathematics and Science Studies (TIMSS 2003), and showed that intrinsic motivation (e.g., "I enjoy learning mathematics.") was positively associated with actual performance in mathematics among East Asian 8th graders in Hong Kong, Japan, Korea, Singapore, and Taiwan and their Western counterparts in Australia, England, the Netherlands, and the United States of America.

Perhaps due in part to Chinese students' outstanding academic achievement (e.g., OECD, 2002), most existing studies concerning intrinsic motivation in non-Western cultures focused on Chinese students' academic motivation. Consistent with the findings from the above mentioned studies based on international data sets, investigations specifically into Hong Kong Chinese primary- and secondary-school students' reading motivation and achievement revealed positive relations from intrinsic motivation (e.g., "I like to read what interests me.") to actual performance (e.g., reading comprehension; Law, 2009; Lin et al., 2012) and engagement

(e.g., amount of time spent on reading or use of reading strategies; Lau, 2009; Law, 2009). When it comes to motivation, engagement, and achievement generally across school subjects, intrinsic motivation has also been found to be positively associated with use of deep-processing learning strategies and self-reported rank of school performance among Hong Kong Chinese secondary school students (Lai et al., 2006). Moreover, positive relations from intrinsic motivation to use of cognitive and metacognitive learning strategies, participation in class, persistence at schoolwork, and actual performance in terms of grades have been evidenced among Taiwan Chinese primary- and secondary school students (d'Ailly, 2003; Shih, 2005, 2008), as well as Korean high school students (Jang et al., 2009). Examining a relative autonomy index, which is a weighted indicator of intrinsic (e.g., "I study the course because it's fun.") relative to nonintrinsic motivation (e.g., "I study the course because I'll get in trouble if I do not."), Vansteenkiste et al. (2005) found that the greater intrinsic relative to nonintrinsic motivation Chinese postsecondary students harbored, the more adaptive their learning experience (e.g., more positive attitude toward the course and better time management) and emotional adjustment (e.g., greater life satisfaction and more positive affect), and the better their exam performance. Also investigating the relative autonomy index, Wang and Pomerantz (2009) showed that the greater intrinsic relative to nonintrinsic motivation Chinese 7th graders harbored upon their entry into junior high school, the better their actual performance in terms of grades one and half years later at the end of 8th grade.

Notably, one study investigated children's intrinsic motivation in a laboratory setting (d'Ailly, 2004). It revealed among Taiwan Chinese 5th and 6th graders nonsignificant relations from interest in a foreign language learning computer game to effort spent on playing the game (as indicated by the computer-recorded amount of time of children's engagement in the game and the computer-recorded number of mouse clicks made by children when playing the game). To summarize, almost all extant empirical research on intrinsic motivation in non-Western cultures focuses on the academic arena and mostly involves East Asian (particularly Chinese) participants. This body of work seems quite consistent (except d'Ailly, 2004) in showing that intrinsic motivation in academic activities is associated with enhanced academic engagement and achievement as well as enhanced emotional well-being among non-Western learners, similar to what has been found among Westerners and lending support to the universal view.

Environmental Influences on Intrinsic Motivation

As to the issue of how environmental factors may affect intrinsic motivation in non-Western cultures, one line of work looks into autonomy-supportive vs controlling parenting or teaching. d'Ailly (2003) revealed a positive relation from mothers' autonomy support (e.g., encouraging children to solve problems in schoolwork on their own, rather than imposing directives upon children) to Taiwan Chinese primary school students' intrinsic motivation. Vansteenkiste et al. (2005) showed that the greater perceived parental autonomy support (e.g., "My parents allow me to choose what to do whenever possible.") vs psychological control (e.g., "My parents are less friendly to me if I do not see things like they do."), the greater Chinese postsecondary students' intrinsic relative to nonintrinsic motivation in learning (i.e., the relative autonomy index). Such a positive relation from perceived parental autonomy support to Chinese students' intrinsic relative to nonintrinsic motivation was evident throughout the first 3 years of college (Pan and Gauvain, 2012). There is also evidence that non-Western students' intrinsic motivation benefits similarly from teachers' autonomy support. Positive associations between perceived autonomy support by teachers (e.g., "My teacher encourages me to ask questions." "My teacher provides me with choices and options.") and students' intrinsic motivation in learning have been found among Taiwan Chinese primary- and secondary school students (d'Ailly, 2003; Shih, 2008), rural Chinese primary school students (Zhou et al., 2009), Korean (Jang et al., 2009), and Russian high school students (Chirkov and Ryan, 2001).

Another line of work scrutinizes particularly the role of personal choice in affecting intrinsic motivation among non-Westerners. In Study 1 conducted by Iyengar and Lepper (1999), 4th graders were let freely decide how much time to spend solving anagrams after a session of working on anagrams in which they were either allowed to make their own choice (i.e., the personal choice condition) or led to believe that their mothers had made the choice for them as to which type of anagrams to do (i.e., the mom choice condition). It was found that Asian American 4th graders spent more time solving anagrams during the free-play period (arguably as an indicator of intrinsic motivation) in the mom (vs personal) choice condition, whereas Anglo American 4th graders spent more time solving anagrams during the free-play period in the personal (vs mom) choice condition. In Study 2 conducted by Iyengar and Lepper (1999), 5th graders were asked to report their liking of a mathematics-related computer game after a session of playing the game in which they were either allowed to make their own choices (i.e., the personal choice condition) or led to believe that their classmates had made the choices for them concerning certain features of the game (i.e., the in-group choice condition). It was found that Asian American 5th graders reported greater liking of the game (arguably as an indicator of intrinsic motivation) in the in-group (vs personal) choice condition, whereas Anglo American 5th graders reported greater liking of the game in the personal (vs in-group) choice condition. These findings have turned out to be perhaps the best known and the most cited support for the culture-specific view on intrinsic motivation – that is, the role of autonomy support (in terms of granting personal choice) in cultivating intrinsic motivation may not be universal.

Bao and Lam (2008) further examined the issue concerning personal choice by studying Hong Kong Chinese primary school students. Their findings depict a refined picture of how personal choice may affect Chinese students' intrinsic motivation: When students feel closely related to their mothers or teachers, there are no differences in their intrinsic motivation in personally vs mother or teacher chosen activities; while when students do not feel closely related to their mothers or teachers,

they tend to have greater intrinsic motivation in personally vs mother or teacher chosen activities. In sum, the majority of the aforementioned studies (except Iyengar and Lepper, 1999) seem to be in line with the universal view that autonomy support from their surrounding environment may help children and students in non-Western cultures to develop intrinsic motivation, similar to what has been found among their Western counterparts.

Concluding Remarks

As reviewed above, the relatively small body of extant empirical research on intrinsic motivation in non-Western cultures may be quite limited in that the majority of it (1) focuses on the academic arena (rather than examining diverse activities in diverse domains of life like in sports and health behavior and in diverse settings like in businesses as research among Westerners has concerned), and (2) involves Eastern Asian (particularly Chinese) participants only (rather than comparing participants from multiple cultures as the few studies based on international data sets did). Hence, even though most of the existing studies seem to support the universal (vs culture-specific) view regarding the implications of intrinsic motivation for psychological functioning and the environmental influences that may affect intrinsic motivation, it is avoided consciously to draw any definite and blanket conclusion here. Instead, several reflections are made below about taking a cultural perspective to understand intrinsic motivation.

First of all, it is critical that cultural analyses are made on the basis of unambiguous conceptualization and operationalization of intrinsic motivation and related constructs, and with full consideration of alternative explanations. As mentioned earlier, in Study 1 conducted by Iyengar and Lepper (1999), time spent on doing the task during the free-play period was taken as an indicator of intrinsic motivation, but this is dubious because it is quite likely that Asian American children would decide to spend more time working on the task in the mom (vs personal) choice condition for nonintrinsic reasons such as to please their mothers. Moreover, while d'Ailly (2004) found nonsignificant relations from Taiwan Chinese children's interest to their effort when they were instructed to play a computer game in the laboratory, it was also found in the study that when explicitly told that there would be no test, Taiwan Chinese children's interest in the game increased significantly. The latter finding suggests a plausible explanation for the former finding such that the laboratory setting may be perceived by Taiwan Chinese children as a test setting in which they tend to exert much effort regardless of interest, while it remains an open question as to the relations from interest to effort among Taiwan Chinese children when they do not feel the pressure of being tested. The foregoing closer look at the studies conducted by Iyengar and Lepper (1999) and d'Ailly (2004) calls for rigorous research across cultures that entails efforts to understand adequately the cultural meanings of the assessments and the procedures, as well as to ensure between-culture measurement equivalence (for reviews on measurement equivalence, see Davidov and Depner, 2011; Vandernberg and Lance, 2000). Also of note is that caution is warranted against mistaking likely universal boundary conditions (e.g., interest plays less of a role in effort expenditure when individuals are under the pressure of being tested) for 'dichotomous' cultural differences in fundamental psychological processes (e.g., intrinsic motivation matters for Western but not Chinese children).

Second, it is essential to theorize and research intrinsic vs nonintrinsic motivation in an inclusive and integrative, rather than exclusive manner – an approach which is inherent in Western-originated theories (see Deci and Ryan, 2001) but often missing in cultural analyses. For instance, the aforementioned findings by d'Ailly (2004) of nonsignificant relations from interest to effort among Taiwan Chinese children are often interpreted as evidence for the culture specificity of intrinsic motivation (i.e., intrinsic motivation may not be relevant in Chinese culture, unlike in Western cultures; see Hau and Ho, 2010), but not as evidence for the universality of the role of nonintrinsic factors (e.g., perceived pressure of being tested) in undermining the functional relevance of intrinsic motivation (see Deci and Ryan, 2001). Also, the findings from the studies conducted by Iyengar and Lepper (1999) that Asian-American children demonstrated greater intrinsic motivation in the mom (vs personal) choice condition (Study 1) or in the in-group (vs personal) choice condition (Study 2) are often highlighted over the findings from the same studies that Asian American children in fact demonstrated greater intrinsic motivation in the personal (vs experimenter) choice condition (Study 1) or in the personal (vs out-group) choice condition (Study 2), thereby downplaying the relevance of personal choice for Asian-American children's intrinsic motivation.

Indeed, the salience of nonintrinsic factors (e.g., pressure of being tested; d'Ailly, 2004) and socially oriented motivation (e.g., great engagement demonstrated by Asian American children in the mom choice or the in-group choice condition; Iyengar and Lepper, 1999) in non-Western cultures has been a major argument for the culture-specific view on intrinsic motivation. However, the functional relevance of intrinsic motivation does not exist exclusively with the functional relevance of nonintrinsic factors (see Covington, 2000) or socially oriented motivation (see Pomerantz et al., 2012). Rather, the social context may facilitate a process termed internalization (see Deci and Ryan, 2001) through which individuals come to find interest, enjoyableness and meaning in activities that do not carry such features initially (see also Sansone and Harackiewicz, 2000). For example, positive relations from attitudes toward family obligations to intrinsic value of schoolwork have been found among adolescents of European, Asian, and Latin American background in the United States (Fuligni and Tseng, 1999).

While stimulated by the apparent contradiction between the theoretical analyses suggesting culture-specificity vs universality regarding intrinsic motivation, this article concludes with the observation that those theoretical analyses (i.e., individualism vs collectivism, independent vs interdependent orientations, or the so-called Socratic vs Confucian approaches to learning, in contrast to Self-Determination Theory or indigenous Chinese notions of learning) may well be compatible when neither culture nor motivation is 'dichotomized'. As pointed

out by other researchers as well, non-Western cultures such as Eastern Asian cultures exemplified by Chinese-originated Confucianism are not monolithic entities of collectivism, interdependent orientation or the so-called Confucian approach to learning, to the exclusion of individualism, independent orientation or the so-called Socratic approach to learning (Gurung, 2002; Lee, 1996; Wang and Li, 2003). Moreover, although clearly differentiable in their antecedents and consequences, intrinsic motivation and nonintrinsic driving forces of behavior coexist in human reality and weigh out dynamically in co-shaping human strivings, depending on individual and situational as well as cultural characteristics (Covington, 2000; Deci and Ryan, 2001; Gurung, 2002; Wigfield et al., 2006). The value of a cultural perspective lies in enriching and refining the understanding of the full humanity by paying due attention to possibly different availability, functionality, accessibility and applicability of various mental attributes and mechanisms across as well as within cultures (Norenzayan and Heine, 2005). Such a value shall not be undermined by obscuring perhaps unwittingly yet quite misleadingly the universality of certain fundamental psychological processes, which quite likely include intrinsic motivation.

Introspection: History of the Concept

Kurt Danziger, York University, Toronto, ON, Canada

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The concept of introspection, in the sense of a dispassionate observation of one's own mental states, first became prominent in the context of eighteenth-century philosophical empiricism. Although its practice was widely rejected as a basis for building a mental science, some late nineteenth century and early twentieth century psychologists advocated its limited use under laboratory conditions. Behaviorists rejected its use under any circumstances, though admitting verbal reports as sources of scientific data. More recent interest in the experimental study of consciousness and its neural basis has revived questions regarding verbal reports on experienced mental states.

The term 'introspection' refers to the self-observation of mental events. Historically, it is a relatively recent term that achieved prominence in the course of debates about the status and the subject matter of psychology as a science. Critics stressed the incompatibility of self-observation and objective, scientific, observation; defenders proposed versions of introspection that could lead to reliable results.

The Philosophical Background

Origins

There is no documented occurrence of the term 'introspection' before the late seventeenth century. Serious discussion of the phenomenon described by this term began a century later and only gathered momentum in the course of the nineteenth century. Positivists like Auguste Comte now began to contrast the reliable, objective methods of science with the speculations of philosophers supposedly based on self-observation. Introspection, thus defined, would be as old as philosophy, a claim that is hardly supported by an analysis of the relevant early texts.

The origins of the modern concept of introspection are closely tied to the rise of an empiricist philosophy at the end of the seventeenth century. For John Locke and others (1690) all knowledge was based on experience, but there were two sources of experience: the external senses and "the perception of our own mind within us," which he likened to an "internal sense." The modern concept of introspection emerged out of the empiricist philosophers' belief that self-knowledge was based on acts of internal observation that were closely analogous to the acts of observation by which we gain knowledge of the external world.

The Classical Controversy

Objections to the empiricist concept of introspection were launched from two entirely different directions, though there was some convergence on specific criticisms. One set of objections came from the German Idealist philosophers, the other from Scientific Positivists like Comte. Among the first group a beginning was made by Immanuel Kant, who gave several reasons why an empirical study of the psyche could never amount to a natural science. Among these reasons was the consideration that one could not observe one's mental states without thereby altering them. This position was based on a rejection of the empiricist analogy between knowledge of the natural world and self-knowledge. At best, self-observation would yield information about the self as it appears to itself, not as it really is. Idealism led to the development of methods of investigation in the human sciences that were neither introspective nor 'natural–scientific' in character.

'Scientific Positivism,' on the other hand, rejected introspection along with any knowledge gained by methods other than those of the natural sciences. These methods demanded a strict separation of the observer and the objects observed; a separation that, according to Comte, no one could achieve in regard to his own mind. Introspection did not merely modify what was observed, it was actually impossible.

Safeguarding the foundations of philosophical empiricism, John Stuart Mill replied to Comte by offering what came to be the classical defense of introspection: Mental events do not disappear in a flash – they are remembered. What is actually observed during introspection are the memories of recently past mental events, not the events as they occur. In other words, introspection is really retrospection, the examination of memory images. This defense was taken over by William James (1890) and other empiricists, though by the closing years of the century their advocacy of introspection was qualified by warnings about possible errors of memory. Some conceptual clarification was introduced by Franz Brentano (1973/1874), who distinguished between the immediate awareness of ongoing mental events, which he called "internal perception," and "self-observation" (the retrospective attending to past mental events). It can be confusing to refer to both as "introspection."

Introspection and Experiment

The turn to experimental methods of psychological investigation was closely linked to the controversial nature of introspection. Wilhelm Wundt, who played a major role in the launching of experimental psychology, believed that the psychological laboratory provided the only conditions under which reliable introspective data could be gathered (Danziger, 1990). He accepted the distinction between inner perception

and self-observation but unlike his predecessors, totally rejected the latter. Instead, he advocated a control of the conditions of internal perception so as to approximate the conditions of external perception. This could be accomplished in the laboratory by such measures as the repetitive presentation of relatively simple stimuli and the requirement that reactions be immediate and automatic. However, adherence to these conditions would necessarily limit the scope of experimental psychology (and of valid introspection) to the investigation of 'elementary' psychological events, mainly in the areas of sensation and reaction times.

At the beginning of the twentieth century, these restrictions were rejected by a new generation of experimental psychologists who greatly extended the scope of experimental introspection so as to enable the investigation of more complex psychological processes like thinking and problem solving. Reliability of results was now thought to depend on the adoption of certain attitudes while introspecting. But there was no unanimity about the nature of these attitudes. E.B. Titchener (*see* Structuralism), a major exponent of experimental introspection, demanded that introspective descriptions should be in terms of simple, irreducible units and should abstract from any meaning that the stimulus might have. In Europe, members of the Wurzburg School (see Humphrey, 1951) emphasized the importance of clearing one's mind of preconceptions while introspecting (Titchener's requirements were prime examples of such preconceptions). Later, the *Gestalt* psychologists extended this phenomenon-based approach by insisting that perceptions should be described exactly as they appear in daily life, i.e., in terms of interrelated, meaningful patterns.

The investigations of the Wurzburg School raised a new kind of question: What is the relationship between the conscious experience of the introspector and the verbal report he or she makes of this experience? In the empiricist tradition it had always been assumed that the relationship was one of description, not different in principle from the description of objects experienced as located outside oneself. However, it now appeared that some of the verbal reports in introspection experiments could not be regarded as descriptions of inner states, they were much more like 'expressions' of these states, e.g., when someone reports feeling: "Oh no, not that again!" The German term for this is *Kundgabe* which has connotations of broadcasting and proclaiming. This distinction pointed toward a recognition of the communicative features of introspective reports. It also suggested that the result of treating introspective reports purely as descriptions of mental events was likely to be a misleadingly intellectual account of such events.

Behaviorism and Its Aftermath

Divergent attitudes to the practice of experimental introspection led to divergent results among different laboratories. Titchener claimed that sensory images could always be discovered in any thought activity but this was disputed by the Wurzburg School, by Binet in France, and by others. This became known as the "imageless thought controversy." Situations in which the results from one laboratory are at variance with those from other laboratories are far from unknown in the history of science. However, the 'imageless thought controversy' acquired a special significance because its existence was used as evidence for the uselessness of introspection by a new movement in American psychology, namely, 'Behaviorism.'

Early behaviorists like J.B. Watson considered introspection to be entirely bogus, while others, like K.S. Lashley, conceded that it might provide "cues to physiological problems." Certainly, no scientific hypothesis could ever be verified by means of introspection. But in retrospect it seems that the behaviorists drew unwarranted conclusions from the practical difficulties of introspection. (Mackenzie, 1977; Howe, 1991). Both pragmatic and metaphysical reasons were operative here. Pragmatically, it seemed advisable to dispense with a practice that would never yield the kind of knowledge that the science of psychology increasingly aspired to, i.e., knowledge that would be useful in dealing with practical psychological problems on a large scale. Metaphysically, the behaviorists were committed to the elimination of mind from the category of things that could have effects in the real world. Therefore, the study of mental events was pointless.

Behaviorism was more successful in denigrating introspection than in offering an alternative explanation of what actually happened when someone claimed to be introspecting. Its attempts to do so generally involved assumptions about the existence of subtle physical processes, like subliminal movements of the vocal cords and other as yet undetectable examples of "covert" behavior. It was these, rather than mental states, that supposedly gave rise to introspective reports. Behaviorism effectively accepted the original philosophical analogy between internal and external observation. It differed from those it called 'introspectionists' only in regard to the kind of stuff that was the target of internal observation.

There was a strong rhetorical element in the behaviorists' critique of introspection, which led to the construction of historical legends. One such legend was that of a category of "introspective psychology" that comprised prebehaviorist and antibehaviorist psychologies in general. This blurred the significant distinctions that existed among those who were not prepared to outlaw all forms of introspection. None of them had characterized themselves as "introspectionists," and all had often been critical of many forms of introspection.

Debates about the nature of introspection reached their height during the first quarter of the twentieth century and were followed by a period during which the topic was usually regarded as a closed chapter in the history of psychology. Subjects in psychological experiments could still be questioned about the reasons for their responses but their replies were treated as "verbal reports," a form of overt behavior, not a description of internal mental events. Theoretical discussions about the nature of introspection were largely restricted to professional philosophers, beginning with Russell, Wittgenstein, and Ryle, and had little or no influence on scientific psychology. One exception was the latter day behaviorist B.F. Skinner (1953) who continued to regard introspective reports as an effect of various forms of covert behavior, but also added the possibility that at times they might be no more than a claim by a person to have accomplished a particular discriminative task. Disappointing evidence in the area of "covert behavior," as well as the unscientific multiplication of highly speculative hypotheses, eventually robbed the behaviorist position of its early plausibility.

Subsequently, the question of introspection resurfaced in the context of computer models of mind and consciousness (Dennett, 1978 *see* Computers: Impact on the Social Sciences). Here, introspective reports were seen as the output of some kind of language processing system that receives input from various sources, notably, one or more memory systems, an attentional–perceptual system, and perhaps a central 'control' system. The nature of the output will depend on the "information" that is in these systems and on their functional interrelationships. In some versions of the model the final subsystem only has access to the results of previous information processing, not the process itself. This accounts for certain inadequacies of introspective evidence; problems of memory account for others (see Ericsson and Simon, 1993).

Some authors pointed to the fact that all experimental introspection and much everyday introspection occurs in a social context and that introspective reports are always limited by the linguistic resources available to the reporter (Lyons, 1986). The content of introspective reports is therefore circumscribed by social and cultural factors.

In the early twenty-first century, a revived interest in the experimental study of consciousness led to a reopening of questions about introspection (see Overgaard, 2006). Attempts at finding the neural correlates of consciousness had been propelled by major methodological advances on the neural side but were hardly matched by greater conceptual clarity on the other side of the correlation.

Abstract

Statistical models, typically consisting of a collection of probability distributions, are used to describe patterns of variability that random variables or data may display. Describing the invariance of such models is often done via group theory. Although the mathematical notion of a group is relatively simple, the ideas of group theory provide a very convenient way to describe how statistical models change when random variables are transformed. In particular, statistical models that are closed under a class of transformations are called invariant. Often this invariance has important implications for inferential problems associated with the model. The principle of invariance asserts that whenever a problem is invariant under a group of transformations, then the solution to the problem should also be invariant. Applications of this principle occur in both estimation and hypothesis-testing problems. For example, maximum-likelihood estimators and likelihood-ratio tests are invariant solutions to inference problems when the model is invariant.

Invariance in Statistics

The use of the word invariance in a statistical context most often refers to situations where a statistical model transforms in a suitable way when potential observations are transformed. Describing this context requires the specification of two ingredients. The first is the collection of probability distributions which specify the statistical model. The second is the group of transformations which describes what type of invariance is under consideration. Using the invariance of a statistical model to suggest inferential schemes, such as estimators or tests of hypothesis, is one of the most important applications of invariance reasoning. Such uses of invariance, via concrete examples, form the connective tissue in this article. These examples provide applications of the *principle of invariance* which asserts that invariant problems should have invariant solutions.

The ideas of invariance provide not only the motivation for many statistical procedures but supply the insight and techniques for establishing both distributional and optimality properties of modes of inference. This is most pronounced in the area of linear statistical models – univariate as well as multivariate. For example, in standard regression and analysis of variance models, the affine invariance is reflected in maximum likelihood estimation, in classical F-testing procedures as given by ANOVA tables, and in the structural equation approach to linear models (Fraser, 1968) (*see* Nonparametric Regression). In addition, nonparametric procedures based on ranks and inference based on permutation distributions receive their basic statistical justification from invariance considerations. A full explication of the role of invariance in statistics requires no mean amount of mathematical and statistical theory. However, much of the motivation and pioneering work can be appreciated without all the formal details. Readers wishing just to get the main ideas are advised to skip Section 4 and focus on the concrete examples given in Sections 2, 5, 7, and 8 of what follows.

An Example Due to E. J. G. Pitman

One of the first full fledged invariance arguments to appear in the statistical literature of estimation is due to (Pitman, 1939). Here is a special case of his argument which provided motivation for later work on invariant estimation.

Example 1. Suppose f is probability density function on the real line R^1. For each real number $\theta \in R^1$,

$$f(u-\theta), \quad u \in R^1 \qquad [1]$$

is a density with a *translation parameter* θ. The density in (1) serves as a *translation model* in some very simple experimental situations. Now, suppose that $X_1,\ldots,X_n$ are independent and identically distributed according to (1). To describe the statistical model for the data $X_1,\ldots,X_n$, first form the $n \times 1$ column vector X with coordinates $X_1,\ldots,X_n$. On Euclidean n-space R^n, X has a density

$$p(x|\theta) = \prod_{i=1}^{n} f(x_i - \theta) \qquad [2]$$

where x is an element of R^n with coordinates $X_1,\ldots,X_n$. eqn [2] gives the likelihood of the data $x = (x_1, \ldots, x_n)'$ where the prime denotes vector transpose. The density p in (2) together with $\theta \in R^1$ specifies the *statistical model* for the vector X.

Now, let c be a real number and consider the transformed random variables and parameter

$$\tilde{x}_t = X_i + c, \quad \tilde{\theta} = \theta + c \quad \text{for } i = 1, \ldots, n \qquad [3]$$

If X has a distribution corresponding to θ, then $-\overline{X} = (\tilde{x}_1, \ldots, \tilde{x}_n)'$ has a distribution corresponding to $\tilde{\theta}$. In other words, if X_i are all translated by c, then the model parameter is translated by c. For this reason the model for X is said to be *invariant under translation*.

Next suppose the statistical problem is to estimate θ. Given an estimator

$$T = t(X_1, \ldots, X_n) \in R^1 \qquad [4]$$

let

$$r_T(\theta) = \mathscr{E}_\theta (T-\theta)^2 \qquad [5]$$

be the mean squared error of T. Here, $\mathscr{E}$ denotes expectation under the distribution of X.

In essence Pitman now argued as follows: *Consider an estimate* $t(x_1,\ldots,x_n)$ *of* θ. *From the invariance of the model,* $t(x_1+c,\ldots,x_n+c)$ *is an estimate of* $\theta+c$. *Thus,* $t(x_1+c,\ldots,x_n+c)-c$ *is also an estimate of* θ. *Equating these two estimates yields*

$$t(x_1+c,\ldots,x_n+c) = t(x_1,\ldots,x_n)+c \qquad [6]$$

for all $X_1,\ldots,X_n$ and all c.

An estimate satisfying (6) is called an *invariant estimate*. Pitman asserted that the invariance of the model strongly suggested that only invariant estimates of θ should be considered. He then showed that, within the class of invariant estimators, there is one which is *best* in the sense that it has the smallest mean squared error (see (5)) for every θ. This best invariant estimate is given by the formula

$$t_0(x) = \int_{-\infty}^{\infty} \theta p(x|\theta)\mathrm{d}\theta \Big/ \int_{-\infty}^{\infty} p(x|\theta)d\theta, \quad X \in R^n \qquad [7]$$

To say that the *Pitman estimator* $T_o = t_o(X)$ is *best invariant* means that if T is any invariant estimator, then $r_{To}(\theta) \le r_T(\theta)$ for all $\theta \in R^1$.

The argument leading to the best invariant estimator T_0 is based on two observations. First, the model given by (2) for the random vector X transforms in a very simple way when the data are translated (see (3)). Second, the problem of estimating θ also transforms in a simple way and rather naturally leads to estimates satisfying (6) – namely, the invariant estimates. Generalizing Pitman's argument to cover other inferential problems is much of what invariance is about, although the earlier work of Hotelling (1936) had already introduced invariance into hypothesis testing. The next sections describe in mathematical terms what is meant by an invariant statistical model. It is helpful to keep the Pitman example in mind.

Statistical Models

Consider an experimental situation which will give rise to a vector $X = (X_1,\ldots,X_n)'$ of observations. In essence, a statistical model for this situation is a collection of probability distributions for X, one of which is supposed to be an adequate description of the potential variability that might be expected in X. Because X is an n-dimensional column vector, the distributions for X are defined on R^n. The collection of distributions is often written $\{P(\cdot\,|\theta)|\theta \in \Theta\}$ and the index θ for the collection is a *parameter*. The set Θ is called the *parameter space*. The collection $\{P(\cdot\,|\theta)|\theta \in \Theta\}$ is the *statistical model* for X. Statistical models are typically based on a detailed knowledge of the science underlying the generation of the vector X, the type of data similar experiments have yielded, plus a variety of other considerations including analytic tractability.

In Example 1, the sample space is R^n, the parameter space is $\Theta = R^1$, and $P(\cdot\,|\theta)$ is given by

$$P(A|\theta) = \int_A p(x|\theta)\mathrm{d}x \qquad [8]$$

where A is a subset of R^n. The density $p\,(\cdot|\theta)$ is given in (2). Therefore $\{P(\cdot\,|\theta)|\theta \in \Theta\}$ is the model for the Pitman example when $P(\cdot\,|\theta)$ is given by (8).

Groups of Transformations

A simple but very useful type of algebraic system is a group. In essence, a *group* is a set G together with a binary operation o so that the following hold:

1. if g_1 and g_2 are in G, then $g_1 \circ g_2$ is in G. Thus G is *closed* under the binary operation;
2. there is an element e in G called the *identity* so that $e \circ g = g \circ e = g$ for all $g \in G$;
3. each element g has an *inverse*, g^{-1}, which satisfies $g \circ g^{-1} = g^{-1} \circ g = e$ and
4. for g_1, g_2 and g_3 in G, $g_1 \circ (g_2 \circ g_3) = (g_1 \circ g_2) \circ g_3$. Thus the binary operation is *associative*.

It is common notational practice to delete the binary operation o and write g_1g_2 for $g_1 \circ g_2$. This convention is followed here. A standard example of a group is the set R^n where the binary operation is addition. A more interesting example is the set Gl_n of all $n \times n$ nonsingular matrices where the binary operation is matrix multiplication. For further examples see MacLane and Birkhoff (1967).

The notion of a group of transformations arises when each element g of a group G can also be thought of as defining a bijective (one-to-one and onto) transformation on a set $\mathscr{X}$. Here are two familiar examples.

Example 2. Take G to be the set of real numbers and the binary operation to be addition. Let $\mathscr{X}$ be Euclidean n-space R^n and let x_0 be a fixed vector in R^n. Each $g \in G$ defines a bijection of R^n to R^n given by $x \to x + gx_0$. Here gx_0 is the real number g times the vector x_0. The above notation means that the function defined by g maps x onto $x + gx_0$. For example, if x_0 consists of the vector of all ones, then $x + gx_0$ is just the vector x with g added to each coordinate. This case arose in Example 1 – see (6).

Example 3. Take G to be all $n \times n$ nonsingular matrices with the binary operation of matrix multiplication. With $\mathscr{X} = R^n$, each g defines a bijective transformation $x \to gx$ where gx is the matrix g times the vector $x \in R^n$.

Although not completely obvious in the above two examples, the group operation 'fits together' with function composition when the group element is thought of as a bijective function. In Example 3, what this means is that

$$A_1(A_2x) = (A_1A_2)x \qquad [9]$$

The left hand side of (9) is the 'function' A_1 evaluated at A_2x. Hence $A_1(A_2x)$ is the composition of the two functions A_1 and A_2 in that order. The right hand side of (9) is the 'function' A_1A_2 evaluated at x where A_1A_2 is the group element formed by composing the two group elements A_1 and A_2. This 'fitting together' is what defines a *group of transformations*.

Let $\mathscr{X}$ be a set, G be a group, and assume each $g \in G$ defines a bijective transformation from $\mathscr{X}$ to $\mathscr{X}$. The value of the transformation g at x is written gx. For notational convenience, the action of the function g on $\mathscr{X}$ is written

$$x \to gx \qquad [10]$$

That is, x is mapped onto gx by the function g.

The group G is said to *act on* $\mathscr{X}$ if

a. $g_1(g_2x) = (g_1g_2)x$ *for* $x \in X$ and $g_1, g_2 \in G$.
b. $ex = x$ *for* $x \in \mathscr{X}$ where e is the identity in G.

Conditions (a) and (b) imply that the group inverse of g is the function inverse of g when g is thought of as a bijective transformation. When G acts on $\mathscr{X}$, G is a *group of transformations*.

In statistical applications, it is common for a group G to act on more than one set in the same problem. This happens in Example 1 where G acts on the sample space R^n as noted in Example 2 and G acts on the parameter space $\Theta = R^1$ (3). More complicated examples are given in the next section.

When the group G acts on $\mathscr{X}$, the set $\{gx|g \in G\}$ is called the *orbit* of x. The orbits decompose $\mathscr{X}$ into disjoint sets. Further, G defines an equivalence relation on $\mathscr{X}$, say $\cong$, where $x_1 \cong x_2$ if and only if $x_1 = gx_2$ for some $g \in G$. The partition of $\mathscr{X}$ induced by $\cong$ consists exactly of the orbits (MacLane and Birkhoff, 1967). A function h defined on $\mathscr{X}$ is called *invariant* if $h(x) = h(gx)$ for all $x \in \mathscr{X}$ and $g \in \mathscr{X}$. In other words, h is invariant if and only if h is constant on orbits. Functions h which are invariant and which take different values on different orbits are called *maximal invariants* because such functions identify the orbits in $\mathscr{X}$. Maximal invariants are important objects in the study of invariant hypothesis testing problems, which are discussed later in this article. Here is a simple example of a maximal invariant.

Example 4. Take $\mathscr{X} = R^n$ and $G = O_n$, the group of $n \times n$ orthogonal matrices. Then G acts on R^n by matrix multiplication of vectors

$$x \to gx, \quad x \in R^n \quad \text{and} \quad g \in O_n$$

The orbits in R^n are $S_r = \{x|x'\ x = r^2\}$ where $r \geq 0$. The orbit S_r is just the rim of the sphere of radius r in R^n. Then $h(x) = x'x$ is a maximal invariant.

Invariant Models

Coupling the idea of a statistical model with that of a group acting on a set leads naturally to the notion of an invariant statistical model. Consider a random vector X with values in a sample space $\mathscr{X}$ and a statistical model $\{P(\cdot|\theta)|\theta \in \Theta\}$ for the distribution of X. The parameter θ may also be a vector. Assume a group G acts on both the sample space and the parameter space, although the action of G on the two spaces may be quite different.

Definition. The statistical model for X is *invariant under* G if for all $g \in G$, when X has distribution $P\cdot|\theta)$, then gX has distribution $P(\cdot|g\theta)$, for all $\theta \in \Theta$.

Example 5. Suppose the real valued random variable X is normal with mean μ and variance σ^2. With $\theta = (\mu, \sigma^2)$, X is $N(\mu, \sigma^2)$ when the parameter value is θ. In this example, the sample space $\mathscr{X}$ is R^1, while Θ is

$$\Theta = \left\{(\mu, \sigma^2)\middle|\mu \in R^1, \sigma > 0\right\}$$

The group G is

$$G = \left\{(a, b)|a > 0, b \in R^1\right\}$$

and the binary group operation is

$$(a_1, b_1)(a_2, b_2) = (a_1a_2, a_1b_2, + b_1)$$

The action of G on $\mathscr{X}$ when $g = (a, b)$ is

$$x \to gx = ax + b$$

while the action of G on Θ is

$$\theta = (\mu, \sigma^2) \to g\theta = (a\mu + b, a^2\sigma^2) \qquad [11]$$

Of course, when X is $N(\mu, \sigma^2)$, then $aX + b$ is $N(a\mu + b, a^2\sigma^2)$. This motivates the group action in (11) and shows that the normal model with arbitrary mean and variance is invariant under the action of G.

The above example is far too simple to be of much interest in inferential problems. A natural extension of Example 5 follows and is of direct relevance in both estimation and hypothesis testing – topics to be considered in sections to follow.

Example 6. The notation established in Example 5 is used here. Suppose $X_1, \ldots, X_n$ are independent and identically distributed as $N(\mu, \sigma^2)$. The random column vector $X = (X_1, \ldots, X_n)'$ takes values in R^n and the distribution of X is the n-dimensional normal distribution $N_n(\mu 1, \sigma^2 I_n)$ where I_n is the $n \times n$ identity matrix and $\mathbf{1}$ is the vector of ones in R^n. The parameter space for this model is Θ given in Example 5. Take G to be the group in Example 5, so G acts on Θ as in (11).

For $g = (a,b) \in G$, the transformation on R^n defined by this g is

$$x = (x_1, \ldots, x_n)' \to ax + b1$$

The model for X is $\{P(\cdot|\theta)|\theta = (\mu, \sigma^2) \in \Theta, P(\cdot|\theta) = N_n(\mu\mathbf{1}, \sigma^2 I_n)\}$. This is an invariant model for X when G acts on R^n and Θ in the manner indicated.

The Principle of Invariance

When a statistical model $\{P(\cdot|\theta)|\theta \in \Theta\}$ on a sample space $\mathscr{X}$ is invariant under a group G, it is common statistical practice to search for good inferential procedures, such as estimation schemes or hypothesis tests, which are also invariant. The normative form of this practice leads to the principle of invariance: If a statistical model is invariant under a group, then invariant inference problems should have invariant solutions.

The argument in Example 1 which led to invariant estimators (Eqn. [6]) is a direct application of this principle applied to an estimation problem. Although a precise definition of what an invariant inference problem is would take us far afield, the estimation and testing examples of the following sections will well illustrate the principle. For a thorough and rigorous treatment of invariant inference problems, see Ferguson (1967), Eaton (1983, 1989), Berger (1985), Lehmann (1986), Lehmann and Casella (1998).

Invariant Estimation

Given an observable random vector X whose distribution belongs to an invariant statistical model $\{P(\cdot|\theta)|\theta \in \Theta\}$, the search for a good invariant estimation of the parameter θ is a common inferential problem. Formally an estimator is a function t defined on the sample space $\mathscr{X}$ and taking value in

the parameter space Θ. The abstract version of the argument used by Pitman is the following:

> The model for X is invariant under the group G so if X has distribution $P(\cdot|\theta)$, then gX has distribution $P(\cdot|g\theta)$. If $X = x$ is observed then $t(x)$ is the estimated value of θ. But if $gX = gx$ had been seen rather than x, then $t(gx)$ should be the estimated value of $g\theta$ since gX has distribution $P(\cdot|g\theta)$. Therefore $g^{-1}t(gx)$ should estimate θ. Equating these two point estimates of θ leads to $t(x)g^{-1}t(gx))$, or equivalently

$$t(gx) = gt(x) \quad \text{for } x \in \mathscr{X}, g \in G \qquad [12]$$

Estimators which satisfy (12) are called *invariant* by some authors and *equivariant* by others. It should be emphasized that in (12), the expression gx means the transformation determined by g evaluated at $x \in \mathscr{X}$ where as $gt(x)$ means g evaluated at the point $t(x) \in \Theta$. eqn [12] involves the action of G on both $\mathscr{X}$ and Θ.

Example 7. The notation and assumptions of Example 6 hold here. The maximum likelihood estimators (MLE) for μ and σ^2 are

$$\widehat{\mu}(x) = \frac{1}{n}\sum_{1}^{n} x_i = \bar{x}$$

$$\widehat{\sigma}^2(x) = \frac{1}{n}\sum_{1}^{n}(x_i - \bar{x})^2$$

Then, written in vector form, the MLE for $\theta = (\mu, \sigma^2)$ is

$$t_0(x) = \left(\widehat{\mu}(x), \widehat{\sigma}^2(x)\right), \quad x \in R^n$$

Thus t_0 is an estimator defined on R^n taking values in Θ. This estimator satisfies eqn [12] so that the MLE is invariant.

Example 7 is a special case of a general phenomenon – namely, when statistical models are invariant under a group, then the MLE is an invariant estimator. This is not to say that the MLE is necessarily a good (or the best) invariant estimator, but just that finding MLEs respects the principle of invariance. For example, the Pitman estimator (7) is usually not the MLE.

Invariant Hypothesis Testing

In multiparameter hypothesis testing problems, it is rather unusual to find a testing procedure with optimality properties when compared with all other tests. However, certain tests in multivariate statistical analyses (Muirhead (1982), Eaton (1983), Anderson (1984)) do have optimality properties within the class of invariant tests when the testing problem is invariant.

Again suppose an invariant model $\{P(\cdot|\theta)|\theta \in \Theta\}$, for $X \in \mathscr{X}$ is given where the group G acts on both $\mathscr{X}$ and Θ. Consider a hypothesis testing problem

$$H_0 : \theta \in \Theta_0 \quad \text{vs.} \quad H_1 : \theta \in \Theta - \Theta_0$$

such that H_0 is the null hypothesis and H_1 is the alternative. This testing problem is called *invariant* if the model under $H_0, \{P(\cdot|\theta)|\theta \in \Theta_0\}$ is also invariant under G. A testing procedure is invariant if it can be expressed in terms of a maximal invariant (see Sect. 4).

Example 8. Let $X_1,\ldots,X_n$ be a random sample from a $N_1(\mu, \sigma^2)$ population and consider the classical Student-t problem of testing H_0: $\mu = 0$ vs. H_1: $\mu \neq 0$. With $\bar{x} = n^{-1}\sum x_i$ and $s^2 = \sum(x_i - \bar{x})^2$, the Student-$t$ test rejects H_0 for large values of $(\bar{x}/s)^2$. This testing problem is invariant under the group $G = \{a | a \in R^1, a \neq 0\}$ where the group operation is multiplication. The action of G on the sample space is

$$x_i \to ax_i, \quad \mathrm{i} = 1, \ldots, n$$

and the action of G on the parameter space is

$$\mu \to a\mu, \quad \sigma^2 \to a^2\sigma^2$$

The Student-t test is not uniformly most powerful (UMP) within the class of all tests but it is UMP within the class of invariant tests (Lehmann, 1986). It is also true that the Student-t test is UMP within the class of unbiased tests – a fact which does not extend to the multivariate case. However, the invariance argument does extend as the following example shows.

Example 9. Let $X_1,\ldots,X_n$ be a random sample from a p-variate normal distribution $N_p(\mu, \Sigma)$. The mean vector μ is in R^p and the $p \times p$ covariance matrix Σ is assumed to be nonsingular. The multivariate analog of the Student-t problem is the hypothesis testing problem H_0: $\mu = 0$ *vs.* H_1: $\mu \neq 0$. Set $\overline{X} = n^{-1}\sum X_i$ and $S = \sum(X_i - \overline{X})(X_i - \overline{X})'$ The likelihood ratio test (LRT) of H_0 *vs.* H_1 rejects H_0 for large values of Hotelling's T^2 statistic (Anderson, 1984) given by up to constants)

$$T^2 = \overline{X}' S^{-1} \overline{X}$$

This is a natural multivariate extension of the Student-t statistic. The above hypothesis testing problem is invariant under the group $G = Glp$ of all $p \times p$ non-singular matrices with matrix multiplication as the group composition. The action of G on the sample space is for $A \in G$

$$X_i \to AX_i, \quad i = 1, \ldots, n$$

and on the parameter space is

$$\mu \to A\mu, \quad \sum \to A \sum A'$$

Hotelling's T^2 test is invariant and within the class of invariant tests, it is UMP.

Example 9 contains elements that are common to a variety of invariant testing problems. First, the LRT is always an invariant test for any testing problem which is invariant. Therefore restricting attention to invariant tests never excludes the LRT. Second, within the class of invariant tests, there is one test that is optimal. This happenstance occurs in some, but certainly not all, invariant testing problems in multivariate analysis (see Eaton, 1983).

Concluding Remarks

The examples given above reflect only the simplest invariance arguments. In fact invariance has found many applications outside the hypothesis testing and estimation contexts

described here. For example, Lehmann (1986) illustrates such arguments in non-parametric problems while other applications can be found in Eaton (1983, 1989), Berger (1985), and Wijsman (1990).

A review of the statistical literature shows that many of the best known statistical procedures have attractive invariance properties. These properties not only appeal to our aesthetic sense of symmetry, but also provide powerful theoretical tools for the study and development of new inferential methods. Although the theory of invariance was well developed by the 1970s, it continues to be an active area of research in mathematical statistics. For example, some recent work in statistical prediction theory has been heavily influenced by invariance considerations (see Eaton and Sudderth, 1999).

Abstract

The nervous system's basic mechanism for communicating information is the opening and closing of ion channels. Ion channels are found in the membranes of cells and different channels allow the passage of different ions such as Ca^{2+}, Na^{+}, K^{+}, and Cl^{-}. In neurons, the Ca^{2+} channel mediates neurotransmitter release, which is the basis for interneuronal communication. The amount of Ca^{2+} entering a channel controls the activity level of neurons, with increased Ca^{2+} leading to increased activity. Excitatory synaptic input increases intracellular Ca^{2+} directly, by activating ionotropic and metabotropic receptors. Ca^{2+} influx also stimulates differentiation and directs the course of development in neurons. Large and sustained increase in intracellular Ca^{2+} on the postsynaptic side of the synapse is the primary event for inducing long-term forms of synaptic plasticity. Excess Ca^{2+} can trigger a cascade of events leading to neural death.

Introduction

The most fundamental mechanism for imparting information in the nervous system is the opening of ion channels. This responsibility begins early in life, where opening of ion channels in progenitor cells induces neuronal differentiation. Indeed, ion channels mold the growth and behavior of neurons throughout each phase of the life span. While there are many different classes of ion channels involved in regulating nervous system activity, Ca^{2+} entry serves as the internal ionic message of neural experience. Developmentally, calcium triggers differentiation, guides the growth of neuronal processes, and contributes to the selective elimination of neurons. Ca^{2+} mediates neurotransmitter release, the simplest form of interneuron communication, and its entry is the primary intracellular event for encoding the frequency and number action potentials generated pre- and postsynaptically. Activity- or use-dependent increases in Ca^{2+} serve as an intracellular message for initiating neuronal plasticity, which may be involved in circuit modifications required for learning a memory. Finally, completing the cycle of neuronal ontogeny, Ca^{2+} in excess triggers a cascade of mechanisms leading to neuronal degeneration during senescence and age-related disease.

Activity-Dependent Increases in Neuronal Ca^{2+}

Internal Ca^{2+} is maintained at extremely low concentrations creating an enormous driving force for its movement into the cytoplasm, from internal stores or the extracellular space. Ca^{2+} levels are estimated to be at about 100 nM in neurons at their resting hyperpolarized state, while extracellular Ca^{2+} is in the 2–3 mM range and 10 μM to 1 mM inside the endoplasmic reticulum (Mattson et al., 2000). The gating mechanisms for Ca^{2+} entry into the cell's cytoplasm include plasma membrane voltage-dependent Ca^{2+} channels (VDCC), plasma membrane neurotransmitter or ligand-activated channels, and Ca^{2+} release from internal stores. All of these mechanisms are recruited by neuronal activity; they experience Ca^{2+}-mediated feedback regulation, and are modulated by neurotransmitter activation of G proteins (Lee et al., 1999; Zhang et al., 1998; Zamponi and Snutch, 1998; Zuhlke et al., 1999). Each mechanism of Ca^{2+} entry is compartmentalized to produce localized increases in intracellular Ca^{2+} and site-specific activation of Ca^{2+}-sensitive pathways (Magee et al., 1998; Neher, 1998; Yuste et al., 2000).

Adaptive thresholds for Ca^{2+} entry ensure its action as a second messenger will reflect high levels of neuronal activity. Voltage-gated and neurotransmitter-gated channels interact during periods of neuronal activity to determine the degree of Ca^{2+} entry and thus the direction of Ca^{2+}-mediated adaptation. The classic sequence for initiating Ca^{2+} entry begins with presynaptic release of neurotransmitter acting postsynaptically to depolarize the cell beyond the threshold for triggering an action potential (Colquhoun and Sakmann, 1998). The pioneering work of Hodgkin, Huxley, and Katz demonstrated action potentials were initiated by activating voltage-dependent Na^{+} channels and rapidly terminated by the combined action of Na^{+} channel inactivation and the opposing activation of voltage-dependent K^{+} channels (Hodgkin et al., 1952). Activation of VDCCs is facilitated by the rapid depolarization initiated by Na^{+} channel activation, but it is not an absolute requirement. High- and low-threshold Ca^{2+}-mediated action potentials can be triggered by depolarization independent of Na^{+} channel activation (Magee et al., 1998; Huguenard, 1996). The duration and peak depolarization of the action potential, and consequently the extent of Ca^{2+} entry, is limited by activation of voltage-dependent K^{+} channels and intrinsic kinetics of Ca^{2+} channel inactivation.

Unique patterns of Ca^{2+} can be achieved by the selective expression of ion channels in different populations of nerve cells. For example, the expression of inwardly rectifying K^{+} (K_{ir}) channels raises the threshold for action potential generation by hyperpolarizing the resting membrane potential of striatal neurons, while the expression and interaction of low-threshold Ca^{2+} channels (T-type), Ca^{2+}-activated K^{+} channels, and hyperpolarization-activated K^{+} channels contribute to regular, intrinsic firing in neurons of the substantia nigra and thalamus (Huguenard, 1996; Santoro et al., 2000; Wilson and Callaway, 2000). Regional differences in ion channel distribution can also create microenvironments of Ca^{2+} control within the cell.

Clustering of Na^+, K^+, and Ca^{2+} channels in dendrites create local sites for integrating synaptic input (Magee et al., 1998; Safronov 1999), and direct association of P/Q- and N-type Ca^{2+} channels with vesicle fusion proteins mediates activity-dependent release of neurotransmitter in synaptic terminals (Goda and Sudhof, 1997; Neher, 1998).

The molecular diversity of ion channels present in neurons creates opportunity for exquisite control of Ca^{2+} influx through differences in gating mechanisms and kinetics of activation and inactivation (Catterall, 1995; Ghosh and Greenberg, 1995). Calcium channels are heteroligomeric complexes containing α_1, $\alpha_2\delta$, and β subunits. Ca^{2+} channels contain a single α_1 subunit, which serves as a pore and voltage sensor. Nine α_1 subunit genes have been identified, corresponding to each type of VDCC channel previously categorized by pharmacology. α_{1a} encodes for ω-Aga IVA-sensitive P-type; α_{1B} encodes for ω-Ctx GVIA-sensitive N-type; α_{1C}, α_{1D}, and α_{1S} all encode for dihydropyridine-sensitiveL-type; and α_{1G} and α_{1H} encode for Ni^{2+}-sensitive T-type calcium channels (Zamponi and Snutch, 1998). K^+ channels represent a much larger and more diverse collection of ion channels. At present, nine families of voltage-activated K^+ channels are described (Kaczorowski and Garcia, 1999). Many are derived from homologues of Drosophila channel genes Shaker, Shah, Shaw, and Shal, referred to as K_V1, K_V2, K_V3, and K_V4, respecively, in mammals. They usually form homotetrameric channels, but association with β-subunits can alter channel kinetics (Kaczorowski and Garcia, 1999). A separate class of K^+ channel fundamental in regulating neuronal excitability is Ca^{2+}-activated K^+ channels. They are classified by single channel conductance of 2–25 pS (small or SK channel), 25–100 pS (intermediate or IK channel), and 100–300 pS (large or BK channel) (Kaczorowski and Garcia, 1999). Ca^{2+}-activated K^+ channels serve as an activity-dependent feedback mechanism for reducing neuron-firing frequency and returning the membrane potential back to its resting state.

Excitatory synaptic input increases intracellular Ca^{2+} directly, by activating ionotropic and metabotropic glutamate receptors (mGluRs), and secondarily by driving the membrane potential beyond the voltage-dependent threshold for activating VDCCs. The cooperation of these mechanisms ensures robust Ca^{2+} signals in response to strong synaptic drive. Ionotropic glutamate receptors (AMPA, kainate, and NMDA receptors) are the postsynaptic mediators of fast excitatory synaptic transmission. Functional ionotropic glutamate receptors contain four or five structurally related subunits. The combination of subunits GluR1–4 makes functional AMPA receptors; GluR5–7 and KA1–2 make kainate receptors; and NR1 and NR2A–D make NMDA receptors (Bigge, 1999). Flip or flop splice variants of AMPA receptor subunits influence gating kinetics. AMPA receptors generally have low Ca^{2+} permeability, due to the Q/R site of GluR2 subunits.

GluR2 is the most common subunit found in the brain, but examples of receptors without GluR2 exist and are implicated in Ca^{2+}-dependent changes in neuronal physiology (Conti and Weinberg, 1999; Bigge, 1999). NMDA receptors have greater glutamate affinity than AMPA receptors, slower activation and deactivation kinetics, and they are highly permeable to Ca^{2+}. The Ca^{2+} conductance/Na^+ conductance is >5 for NMDA receptors, 2 for AMPA receptors lacking GluR2, and 0.1 for AMPA receptors containing GluR2 (Conti and Weinberg, 1999). The combined action of greater Ca^{2+} permeability and slower channel inactivation results in dramatically more Ca^{2+} influx for NMDA receptors. NMDA receptors are made of NR1 and NR2 heterodimer complexes and generally composed of four to five subunits. NR1 is essential for channel function and NR2 confers the voltage-dependent Mg^{2+} block and glycine modulation of NMDA receptors (Conti and Weinberg, 1999). The voltage-dependent Mg^{2+} block acts as an activity sensor, allowing large increases in intracellular Ca^{2+} only when the depolarization threshold for releasing the Mg^{2+} block is exceeded. Kainate receptors, like AMPA receptors, lack voltage dependency. Compared to AMPA receptors, kainate receptors contribute little to the peak postsynaptic response, but their slower decay kinetics results in comparable charge transfer (Ferking and Nicoll, 2000). Kainate receptors also mediate presynaptic inhibition of excitatory and inhibitory synapses in the hippocampus.

Slow excitatory synaptic events mediated by activation of mGluRs is another important mechanism for elevating intracellular Ca^{2+}. Group-I mGluRs stimulate phospholipase C via GTP-binding proteins. Phospholipase C cleaves phosphoinositol-(4,5)-bisphosphate (PIP_2) into diacylglycerol (DAG) and inositol 1,4,5-triphosphate (IP_3). DAG activates protein kinase C (PKC) and IP_3 activates IP_3 receptors located on the surface of the smooth endoplasmic reticulum (Fagni et al., 2000; Mattson et al., 2000). IP_3 receptors trigger the release of Ca^{2+} stored in the endoplasmic reticulum at concentrations of 10–100 μM (Mattson et al., 2000). Other neurotransmitters use the same mechanism for releasing Ca^{2+} from intracellular stores, but glutamate is by far the most ubiquitous.

Transient receptor potential (TRP) channels are a recently described type of channel that was first identified as membrane proteins mediating phototransduction in fruit flies (Hardie and Minke, 1992). In mammals, 28 different TRP channels have been identified and grouped into six subfamilies (TRPA, TRPC, TRPM, TRPML, TRPP, and TRPV) (Wu et al., 2010). TRP channels are unique in that they act as cellular sensors for a wide range of physical and chemical stimuli (Clapham, 2003). TRP channels exhibit a nonselective cation permeability and a weak voltage sensitivity. They are abundant on nerve endings in the skin and mouth as well as throughout the brain in both neurons and astrocytes (Scimemi, 2013). They are sensitive to a wide range of stimuli including Ca^{2+}, cyclic nucleotides, phosphorylation potential, and temperature as well as environmental inputs that can be either beneficial or harmful (Zheng, 2013).

Activation of TRP channels changes the membrane potential and translates signaling ions across the cell membrane. A key feature of TRP channels is their sensitivity to multiple types of distinct stimuli. For example, the TRPV1 channel is sensitive to capsaicin, extracellular pH, and heat, whereas TRPM8 is sensitive to menthol and cold (Zheng, 2013). Understanding how each TRP channel responds to its peculiar set of activation energy is poorly understood and a subject of much research.

Activity-Dependent Control of Neuronal Development

Ca^{2+} influx stimulates differentiation and directs the course of development in excitable cells (Spitzer et al., 1994). VDCCs,

ionotropic glutamate receptors, and mGluRs all participate in regulating intracellular Ca^{2+} at key steps in neuronal development. Glutamate activation of NMDA and AMPA receptors induces proliferation of progenitor cells during neurogenesis and their migration to appropriate cell layers (Haydar et al., 2000). Evidence also exists for neurogenesis mediated by Ca^{2+} entry through voltage-dependent L-type Ca^{2+} channels and Ca^{2+} waves mediated by release of Ca^{2+} from intracellular stores. In postmitotic cells, Ca^{2+} continues to direct neuronal differentiation by influencing ion channel expression, neurotransmitter phenotype, and growth factor expression; and neurite VDCCs (L- and N-types) stimulate cell adhesion molecules (CAMs) (NCAM, cadherin, and L1) to promote neurite outgrowth via CAM-mediated cell-to-cell interactions and the binding of CAM to actin-based cytoskeleton (Doherty and Walsh, 1994). Ca^{2+} may initiate neurite extension by binding to calmodulin (CaM) and phosphorylating microtubule associated proteins (MAP2) through the activation of Ca^{2+}/CaM-dependent protein kinase II and IV (Kuhn et al., 1998). A parallel mechanism implicated in MAP phosphorylation is the mitogen-activated protein kinase (MAPK) pathway stimulated by mGluR activation (Quinlan and Halpain, 1996). It is clear that Ca^{2+}-mediated remodeling is based upon a Ca^{2+} set point, since differences in responses exist depending on the Ca^{2+} level achieved and the neuronal population examined. Some neurons experience growth cone collapse with increases in Ca^{2+}, due to severing of microfilaments by Ca^{2+}-activated gelsolin (Neely and Nichols, 1995). Support for this mechanism comes from the observation of downregulated VDCCs coincident with neurite extension and increases in neuronal activity producing decreases in CAM expression.

Protein synthesis is also critical to activity-dependent plasticity and growth, a process Ca^{2+} mediates through interacting steps of protein phosphorylation (Ghosh and Greenberg, 1995). Activity-dependent increases in Ca^{2+} stimulate the expression of immediate early genes like c-fos and c-jun, as well as delayed 'effector' genes for neurotrophins and, in a mechanism of positive feedback, genes for VDCCs, NMDA receptors, and AMPA receptors (Ghosh and Greenberg, 1995). The pattern of gene expression is dependent on the pattern of neuronal activity and Ca^{2+} accumulation. Intracellular pathways appear to act in parallel to alter gene expression, but they may respond differentially to changes in Ca^{2+} concentration. A final point of convergence for Ca^{2+}-stimulated pathways is phosphorylation of cAMP-responsive element-binding protein (CREB), which activates RNA polymerase by forming a complex with CREB-binding protein. The independent pathways proposed to trigger this mechanism include Ca^{2+} activation of Ras/MAPK pathway, Ca^{2+} activation of adenylate cyclase and subsequently protein kinase A (PKA) and Ca^{2+} binding to CaM, and activation of Ca^{2+}/CaM kinase II and IV (Ghosh and Greenberg, 1995). A clear division does not exist between the actions of Ca^{2+} and neurotrophins in driving activity-dependent change in neurons. Activity not only increases intracellular Ca^{2+}, but it also causes the release of neurotrophins, and neurotrophins and Ca^{2+} produce similar responses in nerve cells (McAllister et al., 1999).

Ca^{2+} and neurotrophins both trigger the Ras/MAPK pathway to change gene expression, neurotrophins by binding to membrane-bound tyrosine kinase (trk) receptors, and Ca^{2+} by activating Ras directly (Heumann, 1994). Neurotrophins have both direct rapid and slow modulatory effects on ion channels involved in excitation (Benedikt and Poo, 1996). Neurotrophins cause rapid depolarization by activating Na^{+} channels linked to trk receptors and they modulate glutamate-activated channels and intrinsic voltage-activated channels to increase intracellular Ca^{2+} (Jarvis et al., 1997; Kafitz et al., 1999). Neurotrophins also increase neuronal excitability and thus Ca^{2+} influx through acute inhibition of $K_{ir}3.1$, $K_{ir}3.4$, and $K_{ir}2.1$ (Wischmeyer et al., 1998). Neurotrophins also act presynaptically to increase neurotransmitter release (McAllister et al., 1999). Testament to the intimate relationship between neurotrophins and Ca^{2+}, neurotrophins produce long-term changes in Ca^{2+} entry by increasing the expression of VDCCs, NMDA receptors, and AMPA receptors, and activity-dependent increases in Ca^{2+} produce a reciprocal increase in neurotrophin expression (McAllister et al., 1999).

The gearing of neurons toward excitation during development is clearly illustrated by the unique behavior displayed by neurotransmitter-activated channels early in development. Embryonic synaptic AMPA receptors are highly Ca^{2+} permeable and miniature excitatory postsynaptic current (mEPSC) amplitude can be more than twofold larger than at mature synapses (Rohrbough and Spitzer, 1999). Postnatal neurons preferentially express flip variants of AMPA receptors, which increase the depolarization-mediated Ca^{2+} signal by slowing desensitization (Conti and Weinberg, 1999). It should be noted, however, that many synapses show only functional NMDA receptors and only with activity to 'silent' AMPA receptors appear (Petralia et al., 1999). Early postnatal development also shows a shift in the molecular structure and physiological properties of NMDA receptors. NR2B subunits are preferentially expressed early in development and they show less voltage-dependent block by Mg^{2+} and slower kinetics, properties which lower the threshold for Ca^{2+} entry during synaptic excitation. With maturity, there is a shift to NR2A and NR2C subunits, which increase the Mg^{2+} block and speed up the NMDA-activated response. This postnatal disposition toward synaptic excitation is augmented by a developmental shift in the property of $GABA_A$ receptor-mediated inhibition (Ben-Ari et al., 1997). Rather than inhibiting action potential generation and VDCC activation, as is seen in adults, immature $GABA_A$ synapses cause slow depolarizations triggering bursts of action potentials and Ca^{2+} influx through VDCCs (Ben-Ari et al., 1997). Later in development, the Cl^{-} gradient changes resulting in hyperpolarizing $GABA_A$ responses and an inhibition of action potential generation and Ca^{2+} channel activation (Ben-Ari et al., 1997).

Activity and Synaptic Function

Ca^{2+} entering presynaptic terminals during action potentials stimulates the fusion of synaptic vesicles with the presynaptic membrane and the release of neurotransmitter into the synaptic cleft. P/Q- and N-type Ca^{2+} channels are the primary VDCCs subserving this function in the central nervous system (Goda and Sudhof, 1997). Entrance of Ca^{2+} through individual channels is proposed to form microdomains, where Ca^{2+} levels may reach as high as 100 μM (Neher, 1998). It is

proposed that 'core complex' proteins of the synaptic fusion machinery maximize their proximity to these domains by binding syntaxin to Ca^{2+} channels (Goda and Sudhof, 1997). Prior to and independent of Ca^{2+} influx, synaptic vesicles dock to the presynaptic membrane in active zones and undergo priming to make them ready for releasing neurotransmitter with Ca^{2+} influx (Goda and Sudhof, 1997). The docking and priming steps are mediated by an interaction of a 'core complex' of NSF attachment protein receptors (SNAREs) located on the vesicle (v-SNARE) and attachment SNAREs located on the target membrane (t-SNARE). The core complex or SNARE is made up of syntaxin and synaptosome-associated membrane protein of 25 kDa (SNAP-25), which are localized in the synaptic plasma membrane, and the vesicular protein synaptobrevin (also known as vesicle associated membrane protein) (Goda and Sudhof, 1997). The process of vesicle fusion and neurotransmitter release is believed to be mediated by the interaction of the synaptotagmin Ca^{2+} sensor with the 'core complex.' Synaptotagmin I and II are the leading candidates as Ca^{2+} sensors, although other presynaptic proteins with Ca^{2+} C_2-binding domains are proposed to serve the same function (Goda and Sudhof, 1997).

The mechanism for fusion is proposed to be a rapid electrostatic or conformational change in the fusion complex mediated by Ca^{2+} binding to synaptotagmin (Goda and Sudhof, 1997). The vesicle collapses into the membrane and is retrieved away from the active zone by a clathrin-dependent mechanism involving the GTPase dynamin I (Cremona and De Camilli, 1997).

Invasion of the presynaptic terminal by multiple action potentials results in a short-term change in the probability of vesicle fusion and the release of neurotransmitter.

Depending on the number and timing of the action potentials, and thus the degree and duration of Ca^{2+} increase, the processes of facilitation (time constant less than 1 s), augmentation (time constant of several seconds), and potentiation (time constant of a few minutes) are initiated (Zucker, 1999). One mechanism proposed for mediating short-term synaptic enhancement is the binding of Ca^{2+} to synapsin I. Synapsin I is a Ca^{2+}-regulated ATPase, which binds to actin and may facilitate vesicle transport via the actin matrix (Zucker, 1999). Other mechanisms proposed to participate in short-term synaptic plasticity include facilitating actions of synaptotagmin and Ca^{2+}-dependent facilitation of presynaptic Ca^{2+} currents (Zucker, 1999). An explanation for the longest form of short-term plasticity, PTP, is based on Ca^{2+} dumping by mitochondria following mitochondrial sequestration of Ca^{2+} during spike trains (Zucker, 1999). New studies indicate another key role for Ca^{2+} in mediating short-term synaptic plasticity lies in a clathrin-independent form of rapid endocytosis of synaptic vesicles. The proposed mechanism suggests that Ca^{2+} binds to synaptophysin during repeated excitation and Ca^{2+}-stimulated synaptophysin binds to dynamin I to produce rapid endocytosis (Daley et al., 2000).

Large and sustained increases in intracellular Ca^{2+} on the postsynaptic side of the synapse is the primary event for inducing long-term forms of synaptic plasticity or long-term depression (LTD) and long-term potentiation (LTP). Critical to determining whether LTP or LTD occurs are the extent and kinetics of the Ca^{2+} signal and the molecular mechanism underlying the Ca^{2+} increase (Zucker, 1999). These factors and other mechanisms vary considerably between brain areas. Based on cortical and cerebellar studies, a few general themes emerge. Ca^{2+} entry through NMDA receptors is a critical event in the induction of LTP and the Mg^{2+} block of these receptors sets a stimulus and depolarization threshold. Weaker stimuli, which activate VDCCs, often lead to the induction of LTD (Zucker, 1999). LTD also requires the activation of group I mGluRs at many synapses and the subsequent activation of nitric oxide synthetase (Daniel et al., 1998). VDCCs can augment the NMDA Ca^{2+} signal if back-propagating action potentials precede activation of NMDA receptors (Zucker, 1999). This receptor-based scheme depends on the parameters of the Ca^{2+} signal, and thus examples of NMDA receptor-dependent LTD and mGluR-dependent LTP also exist (Nicoll et al., 1998).

The mechanisms used to induce synaptic plasticity in adult animals often follow the same pathways utilized for development and growth in the nervous system. Phosphorylation plays a critical role in LTP and it is triggered by Ca^{2+} influx (Soderling and Derkach, 2000). Ca^{2+} activation of Ca^{2+}/CaM kinase and Ca^{2+} activation of the Ras/MAPK pathways play distinct roles in the maintenance phase of LTP.

Autophosphorylation of Ca^{2+}/CaM kinase makes it Ca^{2+} independent and creates a mechanism for maintaining long-term phosphorylation. Active Ca^{2+}/CaM kinase increases AMPA receptor responses and may be involved in the unmasking of silent receptors and the trafficking of new receptors to the extracellular membrane (Malinow et al., 2000; Soderling and Derkach, 2000). Keeping Ca^{2+}/CaM kinase phosphorylated and active is opposed by the activity of protein phosphatase I. Herein lies another critical step in LTP: inhibiting protein phosphates. Phosphatase inhibition is mediated by Ca^{2+} activation of adenylate cyclase, activation of PKA, and phosphorylation of inhibitor 1 (I1). I1 shuts off protein phosphatase I and Ca^{2+}/CaM kinase thus stays phosphorylated and active (Soderling and Derkach, 2000). Another critical component of LTP expression is protein production. Ca^{2+}/CaM kinase is also implicated in gene expression as well as Ca^{2+}-activation of Ras/MAPK and, just like observed developmentally, phosphorylation of CREB (Platenik et al., 2000). Another similarity to development is the clear involvement of neurotrophins in LTP expression. Neurotrophins directly modulate Ca^{2+} physiology and they activate the Ras/MAPK pathway (McAllister et al., 1999; Klintsova and Greenough, 1999).

Ca^{2+} in Aging and Degeneration

The role of Ca^{2+} in development and plasticity requires flawless control over its intracellular concentration. Aging in the brain, and in many other tissues, occurs in part through a disruption in the ability to maintain Ca^{2+} homeostasis (Thibault et al., 1998). A system level theory for explaining aging poses that chronic exposure to glucocorticoid stress hormones creates a disruption of Ca^{2+} homeostasis (Thibault et al., 1998). In the hippocampus, stress hormones and/or aging increases the expression of L-type Ca^{2+} channels (Thibault et al., 1998). The increased Ca^{2+} signal suppresses hippocampal neuron activity by stimulating Ca^{2+}-activated K^+ channels and, consequently, the hippocampus becomes less effective in its role of

terminating the stress response. Circulating levels of stress hormones therefore progressively increase over an animal's lifetime and consequently the deleterious effects of Ca^{2+} overload also become progressively worse. Elevated Ca^{2+} in aged neurons is proposed to create dysfunctional plasticity and to reduce the threshold for Ca^{2+}-mediated cell death.

Disruption of Ca^{2+} homeostasis is also proposed to be a critical event in apoptosis and necrosis produced in many age-related neurodegenerative disorders (Mattson, 1998; Mattson et al., 2000; Thibault et al., 1998). Periods of excessive excitation, as might occur during stroke or in response to β-amyloid stimulation, cause abnormally high levels of Ca^{2+} ions to enter the cell. The candidate mechanisms for the pathological increase in Ca^{2+} influx include VDCCs, NMDA receptor-gated channels, and mGluR activation and downstream release of Ca^{2+} from internal stores. The consequent Ca^{2+} overload stimulates Ca^{2+}-sensitive proteases and it plays a significant role in the generation of reactive oxygen species (ROS) (Mattson et al., 2000). High levels of cytoplasmic Ca^{2+} cause mitochondrial Ca^{2+} loading, which stimulates mitochondrial ROS production and release of apoptotic factors (Mattson, 1998).

The flood of Ca^{2+} triggers abnormal activation of calpain and free radicals activate caspases, both of which are viewed to create excessive proteolysis. In addition, Ca^{2+} sequestration by mitochondria during excessive excitation reduces the production of ATP with a critical cost of shutting down ATPases responsible for maintaining the cell's membrane potential (Albin and Greenamyre, 1992). Plasma membrane Na^{+}–K^{+}-ATPases require huge amounts of energy and their reduced activity leads to cellular depolarization, activation of VDCCs, and the removal of Mg^{2+} voltage-dependent block from NMDA-gated channels.

Ca^{2+} also triggers cytoplasmic production of ROS through the activation of Ca^{2+}-dependent enzymes. Ca^{2+}-activated proteases convert xanthine dehydrogenase into xanthine oxidase, which produces superoxide anions and H_2O_2. High levels of cytoplasmic Ca^{2+} triggered by NMDA-receptor activation also activate nitric oxide synthetase (NOS). NO produced by the activation of NOS is a free radical, as well as a ubiquitous mediator of biological processes (Dawson and Dawson, 1998). NO turns into a much more potent oxidant, however, after it reacts with the superoxide anion under conditions of oxidative stress to produce highly reactive peroxynitrite. The ROS generated by these mechanisms cause lipid, protein, and nucleic acid oxidation and ultimately cell death.

Abstract

For a given population group, the impact of human activity on the natural environment can be decomposed into the per capita impact × population size. Per capita impact, in turn, can be decomposed into the per capita level of consumption or 'affluence' × the environmental impact per unit of consumption under the existing technology. These statements can be combined as the identity $I = PAT$ (Impact = Population × Affluence × Technology). In this form the equation can be attributed to Ehrlich and Holdren (1971, 1972), and is sometimes called the Ehrlich–Holdren equation. IPAT refers to the equation and to the broader view of population–environment relations that it connotes.

'Impact' here indicates a persisting rather than a transitory environmental effect. In Commoner's (1971) definition, it is an external intrusion into an ecosystem which tends to degrade the system's natural capacity for self-adjustment. For population–environment interactions the impacts of most concern are those that reduce the system's capacity to provide environmental services. An example of an environmental impact is a country's carbon dioxide emissions, which degrade the environmental service provided by the atmosphere in regulating heat radiation from the earth's surface. The decomposition in that case would be population × per capita GDP × the 'carbon intensity' of the economy. At a given level of affluence and carbon intensity, emissions rise in proportion to population.

IPAT as a Causal Relationship

The IPAT equation is more widely employed not as an identity, but as a causal relationship, intended to point to the environmental damage that results from one or more of population size, a high-consumption lifestyle, and environmentally destructive technology, each amplifying the others. Implicitly, it asserts that these factors can together be seen as the main human causes of degradation. That assertion is debatable: in particular, social organizational and behavioral factors would often warrant separate scrutiny as causes of degradation rather than being subsumed within A and T.

This causal use is mostly confined to elementary or rhetorical discourse about the environment. A familiar instance is in contrasting the environmental impacts of population growth in rich and poor regions. If per capita energy use is a proxy for $A \times T$, the environmental impact of an additional person in America or Europe consuming at the average level for those societies would be an order of magnitude greater than that of an average person in Asia or Africa – a disparity cited in many popular writings that seek to assign responsibility for degradation or resource depletion. The relationship is also used simply to organize a discussion, sometimes expressed in a more general functional form: $I = f(PAT)$.

If P, A, and T were independent of each other, the multiplicative relationship would be equivalent to an additive relationship among growth rates. In the case of carbon dioxide, the growth rate of emissions would equal the sum of the growth rates of the three components. However, P, A, and T are not independent of each other. For any defined population and environment, they are variables in a complex economic, demographic, and sociocultural system. Each also has major distributional dimensions and is a function of time. Consumption – or any other measure of human welfare – is an output of this system; environmental effects, both intended and unintended, are outputs as well. And even at the global level the system is not autonomous: it is influenced by 'natural' changes in the environment and by environmental feedbacks from human activity.

One kind of dependency among P, A, and T follows from the common situation of diminishing returns: successive increments to population may do more than proportional environmental damage if they require recourse to ever more powerful technologies to maintain consumption levels. The IPAT equation might then be seen as illustrating a best-case scenario. But other kinds of dependency would tend to lessen the impact. For example, as affluence increases, so typically does a society's demand for a clean environment and wilderness preservation – that is, there is a high-income elasticity of demand for environmental quality. This would support a policy response emphasizing conservation or restoration, and the development and adoption of 'clean' technologies. Similarly, population growth rates generally fall, even to negative values, with rising incomes. If such interactions are acknowledged, the PAT decomposition retains heuristic and pedagogical value but does not bear much empirical scrutiny. In particular, it cannot resolve disputes on the relative contributions of factors responsible for environmental degradation.

For this latter task, Preston (1994) has proposed looking at the variances and covariances of the growth rates of I, P, A, and T over different regions or countries. In an illustrative analysis of carbon emission data for major world regions over 1980–90, he finds that population growth makes only a minor contribution to the total emission variance; the major contributors are the growth of A and T, with a substantial offsetting effect from the interaction of A and T. Given the 50% or so increase in global population projected for this century, however, the future role of population growth in carbon emissions is nonetheless important. Detailed studies of this relationship include Bongaarts (1992) and O'Neill et al. (2001, 2010). Important too, of course, are the demographic consequences of any

resulting climate change, such as those working through shifts in food production, disease patterns, and sea levels.

A more sophisticated version of the IPAT formula, more suited to statistical estimation, includes parameters describing the elasticities of impact with respect to the component factors:

$$I = aP^bA^cT^de$$

where a, b, c, and d are to be estimated and e is an error term. This has been termed the STIRPAT equation (York et al., 2003). It has been used in a number of studies in preference to the original formulation, although the fitting process often encounters problems of multicollinearity. At the country level there is some evidence that the population elasticity b (interpreted as the percentage change in impact from a 1% increase in population) is close to 1 for carbon emissions, but may be higher for some other pollutants (see Cole and Neumayer, 2004).

Environmental Spillovers

With a strong management regime or effective community norms and sanctions, population growth in a region need not adversely affect the local environment. Access to a resource can be rationed, behavior strictly governed, or the growth can be diverted elsewhere, usually to urban centers. Ultimately, limits on the environmental services that can be drawn on would be reached and thereafter degradation would probably ensue. Well short of that limit, however, conditions of rapid economic or political change can undermine a management regime or erode norms and sanctions, with adverse environmental results. Excessive deforestation can often be traced to such institutional breakdowns (or to ill-considered efforts at institutional reform) rather than to population growth. In other cases, a resource may have been so abundant that no management or sanctions were needed: this is a setting where the familiar 'tragedy of the commons' may unfold as the number of claimants to the resource or their exploitative abilities increase (see Hardin, 1968).

Environmental effects of human activities may extend well beyond the region of origin, as with the case of acid rain or watershed destruction. In addition to such literal spillovers, trade and other economic relationships among societies may allow adverse effects to be 'exported' to another region: a poorer society may be more willing to incur environmental damage in return for economic gain, or be less able to prevent it. The concept of a community's 'ecological footprint' offers one means of accounting for such displaced effects in terms of the total area required to sustain the community's population and level of consumption (see Wackernagel and Rees, 1996; *see* Carrying Capacity of the Environment). Where the environmental effects involve degradation of a global commons, as with carbon emissions into the atmosphere, an effective response requires devising an international regulatory regime that takes account of economic level, demographic scale, and technological capacity.

At the global level, a calculation of human environmental impact, in the spirit of IPAT, is that of the extent of human domination of various components of the global ecosystem. Examples would include the proportion of the land surface transformed by human activity, the anthropogenic share of atmospheric carbon dioxide, and the proportion of marine fisheries that are fully exploited or depleted (Vitousek et al., 1997). A summary impact measure proposed by Vitousek et al. (1986) is the proportion of total organic material produced through photosynthesis that is used directly by humans or used in human-dominated ecosystems, which they calculated at the time to be around 30% of the terrestrial total and 2% of the marine total. For a critical discussion of the bases of such calculations, however, see Smil (2013: Chapter 11).

Nonlinearities in Environmental Systems

An evident difficulty for impact assessment is the nonlinearity of environmental systems. The Millennium Ecosystem Assessment (2005), a major global study, foresees a future of accelerating, possibly abrupt, and potentially irreversible changes in ecosystems, with important consequences for human well-being. Ecosystems may have multiple equilibria; they may exhibit cyclical or chaotic behavior. Small human populations and primitive technology do not ensure a small environmental impact: in prehistoric times minuscule populations of hunter-gatherers may have been responsible for some mammalian extinctions and possibly for large-scale ecological change following the introduction of new fire regimes (see Martin and Klein, 1984). Ecosystems may be resilient under the pressure of human activity until a point is reached at which there is sharp discontinuous change (see Holling, 1986). Kasperson et al. (1995) identify a series of thresholds in nature–society trajectories as human activity in a region intensifies beyond sustainability: first a threshold of impoverishment, then endangerment, and finally criticality – the stage at which human wealth and well-being enter an irreparable decline.

The thresholds may not be evident in advance. Under some greenhouse scenarios, for example, gradual ocean warming leads to an abrupt shift in the course of ocean currents – possibly over a period as short as a few decades – with major effects on weather patterns and the climates of coastal states. As systems models of the environment, such as general circulation models of global climate, expand in size and sophistication their value in prediction is expected to increase. However, they may always be defeated in this task by the inherent uncertainties created by nonlinearities in nature itself. Application of the precautionary principle, aimed at keeping human environmental impact below the threshold of sustainability, may lower the likelihood of a surprise outcome but cannot eliminate it.

Subjectivity of Impact Assessments

The transformation of natural environments by human activity is typically identified with damage or degradation. In the case of agricultural practices leading to erosion, salination, laterization, etc., that assessment is clearly justified. The spread of crop and forest monocultures is seen as ecologically damaging through the consequent loss of biodiversity and increase in vulnerability. Some human interventions, however, can be seen as positive in ecological terms – and not only in cases of restoration of earlier damage. It is also important to note that scientific judgment in characterizing environmental impact does not necessarily accord

with public sentiment. Radically transformed environments – say, English hedged fields or Balinese rice terraces – may be regarded as aesthetically pleasing, provided their ecological stability (at a new level) is maintained. Indeed, Dubos (1980) notes that some of today's most admired landscapes are products or by-products of human activity, representing 'areas deforested, swamps drained, hillsides gouged of their stones and sand.' Prior to the Romantic age, 'wilderness' tended to evoke feelings of horror more than of beauty.

Thus, it is necessary to distinguish between an environmental impact of human activity as construed by ecologists (summarized in stylized fashion by the *I* of the IPAT equation) and the subjective assessment of that effect. In common usage the environment is nature viewed through human eyes, valued by human preferences. Preferences differ among people and over a person's life; they may be socially constructed; they tend to adapt to or track realities. An environmental impact that is seen by ecologists as an effectively irreversible change in a natural system – for example, extinction of a species or loss of a tropical rainforest, or the much earlier loss of temperate forests – may offer apparently compensating gains at the time and in the locality; the full costs and accompanying regret may only be felt much later or by groups far removed geographically. Moreover, regret wanes as people's expectations adjust to the new environmental circumstances. An active and timely public response in limiting adverse impacts calls for heightened ecological awareness at the various different levels of society and fuller realization that ecological stability and environmental services cannot be taken for granted.

Abstract

Over the past four decades, human reason and rationality has been among the most intensely investigated topics in psychology, cognitive science, and economics. At the heart of this debate is a view of human rationality, often associated with the *Heuristics and Biases* tradition, on which much of our reasoning and decision making is normatively problematic because it relies on heuristics and biases rather than rational principles. In this article we describe briefly some of the evidence that has been invoked in support of this contention and consider some of the more prominent critical responses, especially from evolutionary psychology and dual-process theorists.

The Aristotelian Tradition vs the Heuristics and Biases Program

There is a philosophical tradition, reaching at least as far back as Aristotle, which maintains that man is a rational animal. According to this Aristotelian traditional, human beings are *intrinsically* rational, though of course even the most ardent defender of this view would admit that people's decisions and thought processes are sometimes very irrational indeed. When people are tired, or drunk, or in the grip of rage, they can think and act in ways that no account of rationality would condone. To accommodate this obvious fact, contemporary defenders of human rationality often appeal to a distinction between *competence* and *performance* similar to the one invoked by contemporary linguists (Chomsky, 1965; Samuels et al., 1999). The claim that human beings are rational is interpreted to mean that normal humans posses a rational reasoning competence – a tacit knowledge of normatively appropriate principles for reasoning and decision making. Under ordinary circumstances these principles are reflected in people's thinking and their actions, though sometimes, for various reasons, our performance can fail to reflect this underlying rational competence.

In the early 1970s, however, Amos Tversky, Daniel Kahneman, and a number of other psychologists began reporting findings suggesting that the Aristotelian view of human rationality is seriously mistaken. What these studies demonstrated is that even under quite ordinary circumstances where fatigue, drugs, and strong emotions are not factors, people reason and make decisions in ways that appear systematically to violate familiar canons of rationality on a broad array of problems. Those first surprising studies sparked the growth of an enormously influential research program whose impact has been felt in a wide range of disciplines including psychology, economics, political theory, and medicine. The expression *Heuristics and Biases* is often used as a label for this tradition, since it holds that much of our reasoning and decision making relies on Heuristics and Biases rather than rational principles.

In the sections to follow we will offer some examples of the sort of experimental findings that many have interpreted as showing that the reasoning and decision-making competence of normal humans is *far* from rational. (For more comprehensive reviews of the literature see Dawes, 1988; Baron, 2008; Gilovich et al., 2002.) But first we need to say what standards of rationality are being applied by those who think the experimental findings demonstrate widespread irrationality. Though writers in the Heuristics and Biases tradition rarely offer an explicit and general theory of rationality, the most plausible reading of their work is that they are assuming some version of what Edward Stein (1996) calls the *Standard Picture*. On this view, to be rational is to reason and make decisions in accordance with principles that are based on the rules of logic, probability theory, and decision theory. Sometimes, of course, it is far from clear how these theories are to be applied – a problem that we will return to in Section Do These Studies Have 'Bleak Implications' for the Extent of Human Rationality?. For the moment, however, we follow the lead of those who work in the Heuristics and Biases tradition and assume that the irrationality manifested in the experiments we describe is intuitively obvious.

Irrationality in Reasoning

The Conjunction Fallacy

In what has become perhaps the most famous experiment in the Heuristics and Biases tradition, Tversky and Kahneman (1982) presented people with the following task.

Linda is 31 years old, single, outspoken, and very bright. She majored in philosophy. As a student, she was deeply concerned with issues of discrimination and social justice, and also participated in anti-nuclear demonstrations.

Please rank the following statements by their probability, using 1 for the most probable and 8 for the least probable.

(1) Linda is a teacher in elementary school.
(2) Linda works in a bookstore and takes Yoga classes.
(3) Linda is active in the feminist movement.
(4) Linda is a psychiatric social worker.
(5) Linda is a member of the League of Women Voters.
(6) Linda is a bank teller.
(7) Linda is an insurance sales person.
(8) Linda is a bank teller and is active in the feminist movement.

In a group of naive subjects with no background in probability and statistics, 89% judged that statement (8) was more

probable than statement (6) despite the obvious fact that one cannot be a *feminist* bank teller unless one is a *bank teller*. When the same question was presented to statistically sophisticated subjects – graduate students in the decision science program of the Stanford Business School – 85% made the same judgment! Results of this sort, in which subjects judge that a compound event or state of affairs is more probable than one of the components of the compound, have been found repeatedly since Tversky and Kahneman's pioneering studies, and they are remarkably robust. This pattern of reasoning has been labeled *the conjunction fallacy*.

Base-Rate Neglect

On the familiar Bayesian account, the probability of a hypothesis on a given body of evidence depends, in part, on the prior probability of the hypothesis. However, in a series of experiments, Kahneman and Tversky (1973) showed that subjects often seriously undervalue the importance of prior probabilities. One of these experiments presented half of the subjects with the following 'cover story'.

> A panel of psychologists have interviewed and administered personality tests to 30 engineers and 70 lawyers, all successful in their respective fields. On the basis of this information, thumbnail descriptions of the 30 engineers and 70 lawyers have been written. You will find on your forms five descriptions, chosen at random from the 100 available descriptions. For each description, please indicate your probability that the person described is an engineer, on a scale from 0 to 100.

The other half of the subjects were presented with the same text, except the 'base rates' were reversed. They were told that the personality tests had been administered to 70 engineers and 30 lawyers. Some of the descriptions that were provided were designed to be compatible with the subjects' stereotypes of engineers, though not with their stereotypes of lawyers. Others were designed to fit the lawyer stereotype, but not the engineer stereotype. And one was intended to be quite neutral, giving subjects no information at all that would be of use in making their decision. Here are two examples, the first intended to sound like an engineer, the second intended to sound neutral:

> Jack is a 45-year-old man. He is married and has four children. He is generally conservative, careful, and ambitious. He shows no interest in political and social issues and spends most of his free time on his many hobbies which include home carpentry, sailing, and mathematical puzzles.
>
> Dick is a 30-year-old man. He is married with no children. A man of high ability and high motivation, he promises to be quite successful in his field. He is well liked by his colleagues.

As expected, subjects in both groups thought that the probability that Jack is an engineer is quite high. Moreover, in what seems to be a clear violation of Bayesian principles, the difference in cover stories between the two groups of subjects had almost no effect at all. The neglect of base-rate information was even more striking in the case of Dick. That description was constructed to be totally uninformative with regard to Dick's profession. Thus the *only* useful information that subjects had was the base-rate information provided in the cover story. But that information was entirely ignored. The median probability estimate in both groups of subjects was 50%.

Before leaving the topic of base-rate neglect, we want to offer one further example illustrating the way in which the phenomenon might well have serious practical consequences. Here is a problem that Casscells et al. (1978) presented to a group of faculty, staff, and fourth-year students at Harvard Medical School.

> If a test to detect a disease whose prevalence is 1/1000 has a false positive rate of 5%, what is the chance that a person found to have a positive result actually has the disease, assuming that you know nothing about the person's symptoms or signs? ____%

Under the most plausible interpretation of the problem, the correct Bayesian answer is 2%. But only 18% of the Harvard audience gave an answer close to 2%. Forty-five percent of this distinguished group completely ignored the base-rate information and said that the answer was 95%.

Irrationality in Decision Making

Framing

In a study that is widely believed to illustrate a deeply irrational feature of human decision making, Tversky and Kahneman (1981) presented a group of subjects with the following problem:

> Imagine that the US is preparing for the outbreak of an unusual Asian disease, which is expected to kill 600 people. Two alternative programs to combat the disease have been proposed. Assume that the exact scientific estimate of the consequences of the programs are as follows:
>
> If Program A is adopted, 200 people will be saved.
>
> If Program B is adopted, there is a 1/3 probability that 600 people will be saved, and a 2/3 probability that no people will be saved.

A second group of subjects was given an identical problem, except that the programs were described as follows:

> If Program C is adopted, 400 people will die.
>
> If Program D is adopted, there is a 1/3 probability that nobody will die and a 2/3 probability that 600 people will die.

On the first version of the problem most subjects chose Program A. But on the second version most chose Program D, despite the fact that the outcome described in A is identical to the one described in C.

The Ultimatum Game

Consider a game that works as follows: There are two players, an 'Allocator' and a 'Recipient' whose identities are unknown to each other. At the beginning of the game the Allocator is given a sum of money (say $10) and asked to divide it between himself and the other player. The only restriction is that the Allocator must offer *something*. So, if the smallest unit of money available is $1, then the Allocator must offer at least this much to the Recipient. Once the Allocator has divided the money, the

Recipient gets to decide whether to accept or reject the amount offered. If the Recipient accepts, each player gets to keep the sum specified by the Allocator. If the Recipient rejects the offer, then both players receive *nothing*. The game is not repeated, and the players know from the outset that they will play only once.

On one widely accepted analysis of the problem, it is never rational for a Recipient to reject an offer, since it is better to get *some* money rather than none. If this is right, then it is always rational for the Allocator to offer the Recipient the smallest amount of money possible, since rational Recipients will always accept the offer, and this will maximize the amount of money the Allocator receives. However, in many studies in both developed and developing countries, subjects very rarely make these choices. Indeed, in these studies it is often the case that the modal offer is to divide the money equally. Moreover, Recipients frequently reject offers of less than 25% of the total, preferring instead to go home empty-handed. (For an overview of the literature see Thaler, 1992.)

The Public Goods Game and Costly Punishment

The Public Goods Game is another game that has been widely used to study economic decision making. In one version of this game, four subjects are each given a sum of money (say $10) and are offered the opportunity of contributing some or all of this money to a group fund. Decisions are made without discussion or negotiation, and subjects are told that they will play the game only once with this set of subjects. After all the subjects have had an opportunity to contribute to the fund, the money in the fund is multiplied by a fixed amount (50% for example) and then distributed equally among all the players, regardless of their contribution. On one analysis, a rational agent concerned to maximize his economic gain should contribute nothing to the group fund, since that will enable him to keep his initial $10 and to get 25% of whatever the other subjects have contributed to the fund. However, in many studies it has been shown that this is rarely what subjects do. The majority of subjects contribute something to the group fund, and many subjects contribute more than 50% of the sum they are initially given.

In one frequently used alternative version of the Public Goods Game, subjects are offered the opportunity to 'punish' other players whose contribution to the group fund displeases them. Specifically, after the game described above is completed, subjects are told that they can spend some portion of their game money to take money from another player, even though they, themselves, will not be allowed to keep the money. They might, for example, be permitted to spend $1 to take $3 from another player, under the proviso that the $4 will be kept by the experimenter. Obviously, under such circumstances, both players are worse off financially. Moreover, the game is designed to minimize the collateral benefits to punishers: decisions about punishment are made privately, and subjects are aware that they will not play the game again with the same set of people. Nevertheless, in a manner that runs quite contrary to standard economic analyses, subjects often chose to spend their money to punish other players who have made smaller than average contributions to the group fund (Yamagishi, 1986).

Do These Studies Have 'Bleak Implications' for the Extent of Human Rationality?

The results we have sketched are just a tiny sample of an enormous and growing literature on human reasoning and decision making. But what conclusions about human rationality – and irrationality – should we draw from these findings? On this question opinions are sharply divided. In one often quoted comment, two leading investigators in the Heuristics and Biases tradition claimed that the experimental results have 'bleak implications' for human rationality (Nisbett and Borgida, 1975). Other researchers have concluded that "individuals are generally affected by systematic deviations from rationality" (Bazerman and Neale, 1986). And still others have suggested that the fault may be in our genes, or at least in our evolutionary history – "that people lack the correct programs for many important judgmental tasks…[because we]… have not had the opportunity to evolve an intellect capable of dealing conceptually with uncertainty" (Slovic et al., 1976). But many other theorists have argued that conclusions like these are unwarranted. In what follows we discuss four of the more prominent responses to the 'bleak implications' view and the evidence adduced in its support. (For an extended review of the debate see Samuels et al., 2002.)

Problems with Specific Experiments

There is a substantial literature arguing that one or another experiment in the Heuristics and Biases tradition is flawed and thus does not really demonstrate that the subjects' performance is irrational. Some of the putative flaws are methodological. One charge that obviously has some merit is that it is often less than clear that subjects understand the problem in the way that experimenters want them to. For example, principles of conversational implicature might lead subjects in the 'feminist bank teller' experiment to assume that choice (6) (Linda is a bank teller) means that she is a bank teller who is *not* active in the feminist movement (Schwarz, 1996). Other putative flaws turn on the way that the experimenters propose to apply the normative principles to particular problems. For instance, Gigerenzer (2000) argues that there are typically several different ways in which the principles of statistics and probability can be applied to a given problem and that these different analyses of the problem lead to different answers – or in some cases to no answer at all. If this is correct, then obviously we cannot conclude that subjects are being irrational simply because they do not give the answer that the experimenters prefer.

Darwinian Responses

A second prominent response to the claim that the human mind is prone to 'systematic deviations from rationality' comes from work by evolutionary psychologists. These theorists argue that if we are adequately to assess the extent of human rationality, we need to pay due attention to issues about the evolved structure and function of our cognitive systems. Further, they maintain that attention to such matters provides grounds for rejecting the 'bleak implications' view.

Informational Format

One especially prominent instance of this sort of critique arises in research regarding our ability to reason about probabilities. Evolutionary psychologists proceed by noting that the effective use of probabilistic information would have been highly advantageous to our hominid forebears, and therefore, they maintain, it would be surprising if we had not evolved 'an intellect capable of dealing conceptually with uncertainty'. But, they continue, we should expect this capacity to manifest itself most clearly when probabilistic information is presented in a format that would have been common in ancestral environments. In these environments, probabilistic information would almost invariably have been presented in the form of information about frequencies as opposed to single events. Thus, evolutionary psychologists argue, we should expect people to do much better on probabilistic reasoning tasks if the problems are presented in a frequency format. And it appears that they do. In the 'feminist bank teller' problem, for example, if the description of Linda is followed by a question like this one:

There are 100 people who fit the description above. How many of them are

…

(6) bank tellers?

…

(8) bank tellers and active in the feminist movement?

…

the number of subjects who commit the conjunction fallacy drops from over 90% to only about 10%.

Further evidence comes from Cosmides and Tooby's (1996) systematic exploration of the 'Harvard Medical School problem' discussed in Section Base-Rate Neglect. They showed that subjects find it much easier to use base-rate information rationally on 'frequentist' versions of the problem, like the one that follows.

1 out of every 1000 Americans has disease X. A test has been developed to detect when a person has disease X. Every time the test is given to a person who has the disease, the test comes out positive. But sometimes the test also comes out positive when it is given to a person who is completely healthy. Specifically, out of every 1000 people who are perfectly healthy, 50 of them test positive for the disease.

Imagine that we have assembled a random sample of 1000 Americans. They were selected by lottery. Those who conducted the lottery had no information about the health status of any of these people.

Given the information above:

on average,

How many people who test positive for the disease will *actually* have the disease? _____ out of _____.

On this version of the problem, 76% of subjects – as opposed to the mere 18% in Casscells et al.'s original study – gave the correct Bayesian answer.

Preference Structure

Evolutionary psychologists have also proposed a related response to the claim that subjects who make substantial offers in the Ultimatum Game contribute to the group fund in the Public Goods Game or pay to punish low contributors in the Public Good Game are being irrational. They concede that it may be irrational to make these decisions if one's only goal in these games is to maximize one's financial gain. But, they note, money is not the only thing that people value. Many people also value fairness and thus they assign positive utility both to being fair in their own offers and contributions, and to punishing others whom they judge to have behaved unfairly in these games. Further, since people in many cultures make fair offers in the Ultimatum Game and pay to punish below average contributions in Public Goods Games, some evolutionary psychologists have suggested that this preference for fairness may be innate and pan-cultural (Baumard et al., 2013).

The suggestion that there is a pan-cultural preference for fairness has not gone unchallenged, however. For example, Henrich et al. (2004) conducted Ultimatum Game experiments in 15 small-scale societies, and found that while people in some of these groups made offers that were similar to those made by subjects in previously studied groups, people in other groups exhibited a wide range of behaviors (for instance, among the Machiguenga, a group in the Peruvian Amazon, the modal Allocator offers only 15% of the money provided by the experimenter, and low offers are almost always accepted). Even more surprising are the results of Gächter and colleagues (Herrmann et al., 2008) who found that in a number of societies scattered around the globe subjects in Public Goods Games with Costly Punishment would pay to punish other players who had contributed *more* than average to the group fund. Ongoing research is aimed at explaining these decisions, which appear to be blatantly irrational and to pose a prima facie challenge to the hypothesis that humans have an innate preference for fairness.

Ecological Rationality

In light of findings such as those just mentioned, some evolutionary psychologists have maintained that our normative standards of rationality require modification. Most influentially, Gigerenzer and collaborators have proposed that for many purposes a conception of rationality that they call *ecological rationality* may be more appropriate as a criterion for normative assessment than the Standard Picture typically assumed by Heuristics and Biases researchers (Gigerenzer et al., 1999). On this view, an inferential or judgmental strategy is ecologically rational if it is accurate and efficient on the sorts of tasks that were important in the environments in which we evolved. If we interpret Aristotle's thesis as the claim that *man is an ecologically rational animal*, evolutionary psychologists maintain that there is a growing body of evidence indicating that he was right (Gigerenzer and Gaissmaier, 2011).

Dual Process Accounts of Human Reasoning

Another response to the 'bleak implications' view that has become quite influential in recent years – even among early advocates of the Heuristics and Biases program – comes from dual-process theories of reasoning (Evans, 2008; Kahneman, 2011; Sloman, 1996; Stanovich, 1999). Dual-process theorists accept that people's reasoning and decision making often deviate systematically from appropriate norms of rationality; but they also maintain that there are many contexts in which people perform quite well. More significantly, they advocate a kind of explanation of this pattern that appears to chart a 'middle way' between those who maintain that normatively problematic heuristics are the *only* reasoning resources people possess, and

those evolutionary psychologists who suggest that *all* reasoning is subserved by normatively unproblematic cognitive mechanisms.

Though dual-process theories differ from one another in many details (Evans and Frankish, 2009), they all propose that reasoning and decision making are subserved by two quite different sorts of system. One kind of system is typically characterized as relatively fast, holistic, automatic, largely unconscious, and requires relatively little cognitive capacity. The other is relatively slow, rule based, more readily controlled, and requires significantly more cognitive capacity. Further, systems of the former kind are widely assumed to have emerged relatively early in human evolution and, as evolutionary psychologists suggest, to have been shaped by natural selection to do a good job on the problems that would have been important to our hominid forebears (Stanovich, 1999, 2004). The other kind of system, by contrast, is assumed to have evolved more recently, is more heavily influenced by culture and formal education, and is often more adept at dealing with many of the problems posed by a modern, technologically advanced and highly bureaucratized society (Stanovich, 1999, 2004).

Since the new system requires more cognitive capacity, is more influenced by culture and education, and does not get used automatically, Stanovich hypothesized that there might be significant individual differences in people's ability and inclination to use it. More specifically, he reasoned, people with higher cognitive capacity, as measured by instruments like the Scholastic Test (SAT), and with a cognitive style that emphasizes 'epistemic self-regulation' should do better on tasks that the old system was not designed to handle. Stanovich agrees with evolutionary psychologists that many of the tasks studied in the Heuristics and Biases tradition fall into this category. In extensive studies of these tasks he has shown that, while the average performance on these tasks is indeed quite poor, there are *some* subjects who give the answer that the Standard Picture suggests is normatively correct on *many* of these problems, and these subjects typically have significantly higher SAT scores and score higher on tests designed to detect cognitive styles that include epistemic self-regulation.

If Stanovich and other dual-process theorists are on the right track, then the unbridled optimism sometimes suggested by evolutionary psychologists is unwarranted, since most untutored people do indeed lack the capacity to deal with a wide range of problems that are important in a technological society. But the glum pessimism often associated with the Heuristics and Biases tradition is not warranted either. Since the fast, automatic, and evolutionarily older system requires little cognitive capacity, everyone has the capacity to deal rationally with many reasoning and decision-making problems that were important in the environment in which we evolved. Moreover, since the new, slow, rule-based system can be significantly affected by education, there is reason to hope that better educational strategies will improve people's performance on those problems that the old system was not designed to deal with.

Abstract

In the social sciences, the concept of 'irrigation societies' derives from the view that the construction and operation of large-scale irrigation societies leads to a concentration of power in the state, as argued by Marx and Wittfogel. Thus the control of water is linked to the appearance of many archaic states. Small-scale irrigation systems, on the other hand, often promote egalitarian systems of governance. Contemporary research on irrigation societies consists of case studies; comparative cross-cultural investigations of the relationship between irrigation and power; analysis of the 'design principles' of successful irrigation systems; and studies of the ecological impact of irrigation.

Introduction

The notion of 'irrigation societies' derives from one of the most durable ideas in social science: that the construction and operation of large-scale irrigation systems leads to a concentration of power in the state. An early formulation of this proposition is found in Marx's writings on 'Asiatic societies': "This prime necessity of an economical and common use of water – necessitated in the Orient – the centralizing power of Government" (Marx, 1853, p. 7). In the 1950s, Karl A. Wittfogel (1957) elaborated Marx's thesis, correlating irrigation scale and political hierarchy. Beginning in the 1960s, archaeologists incorporated these ideas into theories of state formation in the Old and New Worlds. The control of water was linked to the appearance of civilizations in Mesopotamia, Peru, the Valley of Mexico, the Indus Valley, China; and to chiefdoms in the prehistoric American Southwest, Polynesia, and elsewhere (Wright, 1986). In the 1970s, sociocultural anthropologists began to take issue with the Wittfogel thesis, noting that in some cases small-scale irrigation systems actually appear to promote egalitarian social systems, not despotic states. Contemporary research on irrigation societies consists of case studies; comparative cross-cultural investigations of the relationship between irrigation and power; analysis of the 'design principles' (Ostrom, 1992) of successful irrigation systems; and studies of the ecological impact of irrigation.

Overview of Irrigation Systems

It is estimated that humanity now uses 26% of total terrestrial evapotranspiration and 54% of runoff that is geographically and temporally accessible (Postel, 2000). Most of this water is used for irrigation. Groundwater use in irrigation is expanding quickly, and almost 40% of the irrigated area is now reliant upon groundwater as either a primary source, or in conjunction with surface water (Siebert et al., 2010). The global total of irrigated land is now estimated to be between 299 and 310 million hectares, with just over 100 million coming from groundwater sources (Siebert et al., 2010). In the past 50 years, there has been an enormous expansion of new irrigation systems. The FAO estimates that the amount of irrigated land roughly doubled from 1961 to 2009 (2011). According to the World Bank, an average of 885 large dams (>15 m high) were constructed per year between the 1950s and the 1980s. Recently, the rate of construction of large dams has begun to decline, ranging between 160 and 310 per year, and this number is expected to decline further because of rising economic, social, and environmental costs (Postel et al., 1996, 2000, World Commission on Dams, 2000, p. 10). But while the rate of increase in large dams is decreasing, the amount of irrigated land is still expected to increase globally by a factor of 1.9 by 2050 (Lobell et al., 2008).

Meanwhile, small-scale, hand-built, gravity-flow canal systems managed by small groups of farmers still account for about 85% of the world's irrigated cropland, according to World Bank estimates. Small-scale systems operated by local irrigators are still used to grow most of the crops in Asia. For example, more than 15 000 systems of less than 50 ha are managed by farmer's associations in Korea (Oh, 1978). In southern India (Andhra Pradesh, Karnataka, Kerala, and Tamil Nadu), more than 125 000 community tanks, many of which are centuries old, provide water for 30% of the irrigated croplands (Sakthivadivel and Shanmugham, 1989; Shah, 2008). More than six million small tanks and reservoirs are managed at the village level in China (Yu and Buckwell, 1991). Similarly, in Morocco, 830 000 ha are irrigated by locally managed systems utilizing perennial flows and seasonal floods, which range in size from 50 to 3000 ha (Abdellaoui, 1989). About a million hectares are cultivated in Nigeria using traditional irrigation or flood-recession systems, while an estimated quarter million hectares of pre-Hispanic Peruvian terraces are still irrigated in the Andean highlands (Mabry, 1996).

Small-scale irrigation systems are also found in the developed world. Fifty thousand local irrigation systems exist in Japan, some in continuous operation since the early seventeenth century, and together constitute about a quarter of Japan's total irrigated area (Takeuchi, 1980). Centuries-old irrigation systems also thrive on the Mediterranean coast of Spain (Glick, 1970), in the Swiss Alps (Netting, 1981), and in the Southwestern USA (Mabry, 1996).

Environmental Constraints on Irrigation

The physical environment constrains the kinds of irrigation systems that can be constructed. Wittfogel's thesis was based on the labor demands imposed by large-scale, premodern canal irrigation systems, fed by large rivers. Such systems, typical of arid and semiarid regions such as those adjoining the Tigris, Euphrates, and Indus rivers, required the coordinated labor of thousands to be constructed and maintained. Tropical, semitropical, island, and desert environments impose quite different constraints, leading to different technical and managerial solutions. Scarborough has proposed an 'accretional' model for the modification of tropical and semitropical environments, where there is great species diversity but little abundance of one specific species in any single niche or patch (1998). Archaic civilizations evolving in these settings adapted to this dispersed resource base in a manner markedly different from that of early states located in semiarid settings with access to large rivers. According to Scarborough, the political economies of tropical archaic states took advantage of the interconnectivity of dispersed resources, discovering and refining the ecological pathways that made useable resources accessible to humans. For example, the civilizations of the archaic Lowland Maya, and in many regions of South and Southeast Asia developed irrigation systems based on tanks designed to capture wet-season flows and release them in the dry season. Such tanks are still in use in southern India and Sri Lanka.

Oasis civilizations of Central Asia, China, and Arabia developed tunnels called *qanats* to capture the snowmelt from the Himalayas and other mountain chains, transporting the flow for great distances under the deserts. In parts of North Africa, including the Nile Valley and the American Southwest, flood-recession systems were invented to capture and control scarce seasonal rainfall. Mandelbrot and Wallis showed that the annual flood of the Nile River exhibits chaotic behavior (1968). Using this historic data from the Nile as well as modern data from the Senegal river basin, Park has argued that farmers adapted to the risks of too much or too little water by creating institutions to reallocate land among cultivators annually, fostering control by the elite and class stratification long before population pressure reached significant levels (1992).

Management of Irrigation

The relationship between the technical and social aspects of irrigation is an ongoing topic of research. There are two major schools of thought. One tradition, emanating from Wittfogel and pursued primarily by archaeologists, is concerned with the power-centralizing effects of large-scale irrigation systems. A second tradition approaches small-scale irrigation systems from the perspective of common property management (or 'common-pool resources'). A key issue for both research traditions is the relationship between the scale of irrigation systems and the structure and complexity of management institutions. Hunt distinguishes between 'irrigation communities' and 'water–user associations': the former are autonomous, self-contained organizations that are supported by consensual, mutually beneficial institutional arrangements while the latter are units within larger bureaucratic structures that require communication and coordination across organizational levels (1989).

It appears that many small-scale systems of irrigation management are self-governing. Hunt compared 15 irrigation systems in industrialized and developing countries, ranging from 700 to 30 000 ha in extent, and found no strong relationship between system size and the structure of authority. But he predicted that any system larger than about 100 ha has a 'very high probability' of being managed by a 'unified administrative authority structure' (Hunt, 1988, p. 347). Netting argued that water scarcity can be a stimulus for the centralization of decision making, when it threatens widespread conflict that will seriously reduce the efficiency of the system (1981). Kappel identified 5000 as the upper limit of the number of people who can be supported by local self-governing systems, based on a study of 17 historic and contemporary cases. However, Uphoff found that irrigation systems with command areas of up to 40 ha tend to be managed by the entire group of irrigators; those between 40 and 400 ha are managed by a central official, either elected by the irrigators or appointed by the state, and systems between 400 and 4000 ha often have three layers of management (Mabry, 1996).

Turning to the dynamics of management in small-scale irrigation systems, Ostrom notes that 'a self-governing irrigation system is a prime example of a public enterprise in which a segment of society governs itself for itself' (1992, p. vii). A frequent starting-point for the analysis of irrigation communities is Hardin's 'tragedy of the commons' thesis, which holds that rational self-interest will motivate individuals to take as much of a common resource as possible (1998). This is linked to the 'tail-ender' problem in irrigation systems: irrigators closer to the source can control the flow to their downstream neighbors, so the farmer at the tail end is always vulnerable. How then are sustainable cooperative systems of water sharing possible?

One answer is suggested by game theory, specifically the iterated Prisoner's dilemma, which shows how it can be in one's interest to cooperate with other users if there is an expectation that such cooperation will result in continuing access to a valuable, shared resource. Irrigation systems not only provide benefits, they typically entail high labor costs, and this can also be a motive for cooperation. Ostrom found that in negotiations over the rules of water use between the members of a local water–user association, the bargaining power of tail-enders is greater if their labor is needed to maintain the system (1992). Bardhan also found that caste homogeneity increased the likelihood of cooperative behavior in irrigation systems in Tamil Nadu (2000).

Ecological factors may also influence patterns of cooperation. Rice farmers on the Indonesian island of Bali must cope with a suite of rice pests, including rats, insects, and bacterial and viral diseases. The traditional method for controlling these pests is to plant large blocks of rice terraces at the same time. After harvest the fields are flooded, depriving the pests of their habitat, and in some cases killing them outright. Thus upstream farmers, who control the flow of water, may benefit by cooperating with their downstream neighbors. In this way, the scheduling of irrigation can be used to manage pests (Lansing, 1991, 2006).

Irrigation and Agroecology

Salinization resulting from overirrigation and poor drainage has significantly reduced yields on more than 60 million hectares, about a quarter of the total worldwide, and 25 million hectares have been abandoned because of salt accumulation (Mabry, 1996, p. 229). The amount of salinized irrigated land varies greatly from area to area, ranging between 10 and 50% across nations (Goudie, 2003). Annually, for every additional hectare brought into production by new irrigation projects, another goes out of production because of salinization (Umali, 1993). In ancient Mesopotamia, irrigators may have developed successful strategies to slow the rate of salinization (Altaweel and Watanabe, 2012).

Flowing water can pick up and transport mineral nutrients needed by plants, such as nitrogen, phosphate, and potassium. Traditional Asian rice paddies use irrigation systems to bring these nutrients, as well as water, to the plants. For example, volcanic ash from Indonesian volcanoes contains about 1% potassium, and relatively high levels of phosphate. Until the advent of the 'Green Revolution' in rice in the 1970s (the spread of high-yielding crops designed to rely on chemical fertilizers), most of the nutrients needed in Asian rice paddies were supplied by this process of mineral leaching. In Western Europe and the USA, the spread of 'Green Revolution' farming techniques has created an overabundance of nutrients: too much of a good thing. Worldwide, between 1960 and 1980 the application of nitrogen fertilizers increased more than fivefold, and in the decade that followed, more synthetic fertilizer was spread on land than had been applied in the entire previous history of agriculture. Rivers like the Mississippi and the Colorado acquire heavy loads of nutrients like phosphate, and generate enormous pollution problems downstream. For example, in 2009, 21 756 square kilometers of the deep waters of the Gulf of Mexico became a 'dead zone' (Nixon, 1998). European countries like the Netherlands restrict fertilizer use in order to protect freshwater ecosystems, but meanwhile pollution problems have scaled upward from lakes and streams to the Baltic and North Sea. Worldwide, virtually all coastal zones are experiencing rapidly increasing pollution from agricultural runoff and domestic waste (Diaz and Rosenberg, 2008). Archaeologists generally agree that environmental problems associated with the expansion of irrigation systems led to the decline of many ancient states. Today, the spread of irrigated agriculture on which the continuing expansion of the human population depends poses a 'tragedy of the commons' problem on a global scale (Lansing and Kremer, 2011).

Islam: Asia

Abstract

The majority of the world's Muslim population is located in South, East, and Southeast Asia. Muslim control of overland and ocean trade routes linking the Mediterranean basin China and the Spice Islands of eastern Indonesia brought Islam to East and Southeast Asia. Afghan conquests were largely responsible for the establish of Islamic political authority and the spread of Islam among the populations of South Asia. Relationships between religion, including Islam, and ethnicity in the region are complex and highly variable. In societies and states with Muslim majorities ethnic distinctions among Muslims are socially and politically significant. In those with Muslim minorities, particularly China, India, Burma, and the Philippines, 'Muslim' is often regarded as an ethnic as well as religious category. Everywhere there is a dynamic tension between universal Muslim values and legal norms encoded in Arabic and other religious texts and those of local cultures. This tension is expressed in many cultural domains ranging from ritual performance to concepts of political authority. Contemporary 'Islamist' or 'fundamentalist' movements are attempts to shift the balance between local culture and Islamic universalism in the latter direction.

Islam is often understood as a Middle Eastern and, even more narrowly, an Arab religion. While the origins and core scriptures of Islam are indeed Arabic, the majority of the world's Muslim population is located in South, Southeast, and East Asia. This article concerns the Islamicate civilizations and societies of these regions. It examines theoretical and methodological approaches to the study of Islam in the region, the historical processes through which Islam came to be an Asian religion, relationships between ethnicity and religion in Asian societies, popular religion and vernacular literatures in Islamic Asia, the diverse roles played by Islam and Muslims in public life in contemporary Asian States, and the significance of Islamist or fundamentalist movements.

'Islam' and 'Muslim' Definitional and Theoretical Concerns

In both western and Muslim writing the terms 'Islam' and 'Muslim' are used in various and often contradictory ways. Conflicts concerning their use and definition are apparent in, and have done much to shape, scholarly discourse about religion and culture in Muslim Asia. In a theological sense the term Islam means 'submission to god.' A Muslim is a person or *jinn* (spirit) who practices submission. Debates concerning the meaning of submission are a central feature of Islamic discourse. Muslim jurists define Islam as an all encompassing behavioral code and do not distinguish between religious and other modes of social behavior. Mystics (*Sufis*) define Islam as an emotional or spiritual state and are less concerned with personal and social behavior. Proponents of both positions often describe their opponents as *kafir* (non-Muslim).

The line between social scientific and confessional scholarship in and about the Muslim world is a fine one. Many social scientific studies share the Muslim juristic assumption that Islam is first and foremost a legal tradition and that there is a universal and normative core against which the 'Islamicness' of particular cultures can be evaluated. The result has been that societies in which the influence of Muslim mysticism predominates have often been described as nominally and even trivially Muslim (see, for example, Snouck Hurgronje, 1906; Geertz, 1960). Since the early twentieth century many of the basic reference works on Islam in European languages has been written by Muslim apologists whose definitions of 'Islam' are theological motivated (for a contemporary example see Rahman, 1980). For the most part their works assume a legalistic understanding of Islam. To the extent that the social science literature has been shaped by these works, it employs Muslim theological categories. Muslim scholars have, in turn, begun to use social scientific works by Western scholars with whom they are inclined to agree, as authoritative references in overtly apologetic treatises.

Recent scholarship has challenged this approach and the related view that Arabs are the guardians of Muslim orthodoxy. Increasingly, social scientists and textualists have been concerned with the dynamic tension between textual and lived Islam in diverse cultural and historical settings. The textual tradition is now understood as the product of discursive practice. Recent scholars have examined the ways in which this tradition describes, and argues for, a variety of possible 'Islams.' This perspective attempts to capture both the variety of Islamic texts and cultures and historical and doctrine linkages among them. The term 'Islamicate' is now used in reference to societies and civilizations whose development has been shaped by the interaction of Islam, as a religion, and a variety of local cultures. The use of this term circumvents concerns with orthodoxy inherent in early scholarship.

The chief difficulty with this approach is that by privileging the local character of Muslim discourse, it runs the risk of accepting the local as normative. Progress in understanding the local Islams of Asia, and elsewhere, will require additional attention to the ways in which elements of the pan-Islamic textual tradition are interpreted, understood, and put into practice, and alternatively the ways in which specific histories and cultures constrain and limit the implementation of the social ideals described in universally recognized Muslim texts. There is also a need for comparative studies of the various Asian Islams.

Historical Background

Political, economic, and military factors all contributed to the establishment of Islam as an Asian religion and the foundation

of Asian Islamicate civilizations. In the seventh and eighth centuries Arab Muslim armies carried Islam into central Asia and western India. Muslim military traditions resulted in the conquest of most of South Asia. Here, Muslim expansion was motivated as much by the religious conviction that Muslim rulers have an obligation to expand the Muslim world (*dar al Islam*) as by economic considerations. Commerce spread Islam further. Arab control of the western terminus of overland and maritime trade routes linking the Mediterranean basin and China led to the expansion and consolidation of Islam in Central, East, and Southeast Asia.

South Asia

There has been a prominent Muslim presence in what are now Afghanistan and Sind (western Pakistan) since the early eighth century. It was not, however, until approximately 1000 CE that the conquest of the plains of what is now India began in earnest. A long series of raids and invasions based in Afghanistan led to the establishment of Islamicate empires centered in the Gangetic plain. The expansion of Muslim polities continued until the establishment of British power early in the eighteenth century. The Central Asian origins of South Asian Islam account for Turkish and Persian influences on South Asian Muslim literature and popular religion and for the presence of a significant *Shia* minority not found elsewhere in Asia. British conquest of Burma in the nineteenth century (1825–85) led many South Asian Muslims to emigrate to this Southeast Asian nation. Arab Muslim traders reached the southwest coast of India and Sri Lanka in the eighth century. Here, trade, rather than conquest, was the primary factor facilitating the expansion of Islam. The Islamicate cultures of this region resemble those of Southeast Asia and southern China more closely than those of northern portions of the Indian subcontinent.

Southeast Asia

Islam came to Southeast Asia in the thirteenth century. It was brought to the Malay world by Arab and South Asian Muslim traders who dominated the Indian Ocean trade during that period. Muslim states were established on both sides of the straits of Malacca and later spread southward to Java and as far east as the southern Philippines. Largely owing to the power of coastal Sultanates it rapidly became the dominant religion in the Malay-speaking world. Muslim communities in Vietnam, Cambodia, southern Thailand, and Burma originated in similar ways, but never displaced the political dominance of Indianized and, in the case of Vietnam, Sinicized states. Islam came to Burma from two additional sources in the precolonial period, from Bengal in the west and from Southern China. During the period of British rule large numbers of south Asian Muslims migrated to Rangoon, Mandalay, and other Burmese urban centers. There are also scattered Chinese Muslim populations in northern regions of Thailand, Laos, and Vietnam.

China

Arab Muslim armies reached China's western border in AD 714. Muslim control of the silk road stretching across central Asia to western China was the avenue through which Islam came to be the religion of the various Turkic-speaking communities of central Asia, and substantial portions of northwestern China. The Mongol conquest of China and the Islamic lands of central Asia promoted closer contacts between China and the Middle East. The Mongol conquest of Persia and the sack of Baghdad in 1258 CE was a devastating blow to Islamicate cultures. However, the subsequent conversion of the Mongol elite to Islam enhanced the position of Chinese Muslim communities and resulted in the Islamicization of most of central Asia.

Legends preserved by Muslims in Southeastern China speak of Muslim emissaries and traders arriving during the lifetime of the Prophet Muhammad. While the veracity of these accounts is difficult to determine, Chinese records and archaeological evidence point to a significant Muslim presence in Southern China from the seventh century onwards. Muslims played a major role in Chinese international and internal commerce and politics from the eighth century until the establishment of the Ching dynasty in 1644. Muslims were a sizable and 'convenient' minority. Islam enabled them to establish and maintain relationships with the outside world that was both feared and belittled by the Chinese elite. At the same time Islam precluded its adherents from competition for political power within China. Javanese and other Southeast Asia chronicles mention China, as well as Arabia and India, as being among the sources of Islam. This speaks of the importance of the premodern Asiatic commercial system in the expansion of Islam in Asia.

Islam and Ethnicity in Asian Societies

Sociologically, religion and ethnicity are closely intertwined in the Asian Muslim world, though in complex and varied ways. In some instances Islam transcends ethnic distinctions, in others Muslim communities are divided along ethnic lines, despite the normative doctrine and political ideology of 'Muslim brotherhood.'

In nation states with Muslim minorities 'Muslim' has become an ethnic, and often political category, even where Muslims themselves would not recognize it as such. In China, the Philippines, and the Buddhist societies of mainland Southeast Asia, majority populations and governments define Islam as an ethnic category, despite linguistic and religious differences within the Muslim community. Burma provides a clear example. As the result of the inclusion of Burma in the British Indian empire, the Muslim community is extremely diverse. In addition to communities with historical ties to many regions of India, there are Chinese and ethnic Burmese Muslim communities. Typically each of these communities has its own mosque and religious officials. Burmese Buddhists and the national government ignore these distinctions and categorize all of these diverse communities as simply 'Muslim.' In nation-states with Muslim majorities Islam is generally understood as a unifying force that transcends ethnic differences.

In colonial and postcolonial societies Islam has often been used as a unifying ideology. The use of Islam as an organizing principle contributed to the rise of nationalist movements in British India and Malaysia and the Dutch Indies (Indonesia). The effectiveness ofIslam as a political principle has proved to be uneven. It was largely responsible for the division of British India into the states of India and Pakistan in 1949. It provided the basis for Malay nationalism in Malaysia, but also contributed to

Singapore's succession and for ongoing tension between Malay Muslim, South Asian Hindu, and Chinese communities.

South Asia

Religion and ethnicity have long been salient features of social and political discourse in South Asia. Pakistan was founded on the basis of a common religious identity, obscuring ethnic and cultural relationships between Hindus and Muslims in both the Northwest and Eastern regions as well as ethnic and linguist differences among Muslims. Pakistan subsequently split into Pakistan and Bangladesh, a division that reflects, geographic, ethnic, and linguistic differences. Bangladesh is an ethnic as well as a religious state. Pakistan is a multiethnic state that uses Islamic ideology to transcend ethnic divisions. The rise of militant Hindu nationalism as a potent political force in India has led to the identification of Islam and Muslims as an ethnically distinct and 'foreign' element of Indian society. Contemporary Indian Muslims are inclined to disregard sectarian and ethnic differences in the face of a mounting tide of Hindu religious nationalism.

Southeast Asia

Southeast Asia is characterized by extreme ethnic and religious diversity. Islam is the dominant religion in Indonesia, Brunei, and Malaysia. There are important Muslim minorities in the Buddhist countries (Burma, Thailand, Laos, and Cambodia), Sinicized Vietnam, and the Christian Philippines.

The role of Islam in the political systems of the majority Muslim nations of the region, Indonesia, Malaysia and Brunei differs fundamentally. Malaysia is officially an Islamic state, although little more than 50 percent of its citizens are Muslims. Political parties compete to appear 'more Islamic than each other.' Despite the fact that it is the world's most populous Islamic nation, Indonesia defines itself as being neither a religious or a secular state, but rather as one with the state ideology *Panca Sila* (the Five Principles) which comprise: belief in the one true God, a just and civilized humanity, national unity, democracy based on consensus of the people, and wise leadership and social justice for all of the Indonesian people. This ideology seeks to transcend religious differences in a Muslim state in which there are small, but important, Christian and Hindu minorities. Islamic political parties, several of which advocated the creation of an Islamic state, play significant roles in Indonesian politics. These groups understand Islam as an ideology that transcends ethnic distinctions. Other, more liberal, Muslim organizations have attempted to establish an Islamic theology of tolerance promoting ethnic and religious pluralism. Brunei is by far the smallest of the Muslim states of Southeast Asia. It is officially defined as a Malay Islamic Monarchy. Power is located with the Sultan and members of his immediate family. The current Sultan is known as a pragmatist and has sought to limit the influence of Muslim scholars and fundamentalists.

Other Southeast Asian nations have significant Muslim minorities. There is, however, considerable variation in the social and economic status of Muslim minority populations. There is a basic distinction between immigrant and native Muslim communities, that is, between those who define themselves in terms of ethnic categories indigenous to the region and those of Arab, Persian, and South Asian origin. The largest communities of native Muslims are found in the Southern Philippines and Southern Thailand. While Muslims make up less than 10 percent of the Philippine population, they are concentrated in the Sulu archipelago and the southern Island of Mindanao. Phillippino Muslims are culturally and linguistically related to those of eastern Indonesia and the Indonesian/Malaysian island of Kalimantan (Borneo). They fiercely resisted both Spanish and US colonialism and have never been fully integrated into the modern Philippine state. The conquest of these territories was not completed until 1914. The modern state has continued the anti-Islamic policies of Spanish and US colonialists, and encouraged Christian immigration to Muslim majority areas. The result has been continued armed struggle between the army and the Moro National Liberation front. Muslims make up approximately 10 percent of the population of Thailand and are of diverse ethnic origin. Most of the Muslim population of the Southern provinces are Malay, although there are also significant Muslims of the Thai origin. Much of this area was not part of the Thai state until the mid-nineteenth century. There are still periodic outbreaks of resistance to Thai rule. In the vicinity of Bangkok there are diverse Muslim communities of Malay, Thai, Persian, and Cham (Cambodian) origin. In the northern region there is a substantial community of Chinese Muslims originating in Yunan. In general the Thai Muslim community is not well organized as it faces continuous pressure to assimilate Thai cultural norms and Theravada Buddhism. Prior to the Khmer Rouge persecutions there were approximately 500 000 Cambodian Muslims Most are the descendants of Muslim refugees from the kingdom of Champa which was destroyed by the Vietnamese in the fifteenth century. They retain distinct ethnic and linguistic identity. Very few survive.

China

Chinese Muslims (*Hui*) are recognized by the People's Republic as an official nationality, despite considerable cultural and religious differences within the community. Some southern Chinese communities that trace their descent to Arab Muslim traders have sought to be officially recognized as *Hui* to obtain economic benefits granted to minority nationalities. Descent and refusal to eat pork are the primary factors distinguishing them from the larger *Han* Chinese community. In northwest China Turkic Muslim communities employ a combination of ethnic and religious criteria to distinguish themselves from the *Han* majority. The collapse of the Soviet Union led to an Islamic revival among the Turkic people of central Asia. This has led to an increased concern with ethnic and Islamic identity among the Muslim peoples of northwest China. The Chinese Nationalist government of Taiwan views relationships between religion and ethnicity differently than the People's Republic. It does not officially recognize the distinctiveness of Muslim Chinese. Nor does it limit or regulate expressions of Muslim religiosity.

Popular Religion and Vernacular Literatures

Arabic religious texts are known throughout Islamicate Asia. The *Qur'an Hadith* (traditions attributed to the Prophet

Muhammad), legal, mystical, and theological works are studied in theological academies throughout the region. There are also significant vernacular literatures in Urdu, Bengali, Tamil, Javanese, and Malay. Vernacular literatures are often based on a combination of pan-Islamic and pre-Islamic components. Many recount tales of the spread of Islam and the exploits of local Muslim saints, kings, and warriors. Throughout the twentieth century there have been concerted efforts to translate Arabic theological texts into Asian languages. This has contributed to an increased awareness and appreciation of Islamic theology and law in almost every Asian Muslim society.

The ritual complex mandated by Islamic law – the five daily prayers, alms, fasting during the month of *Ramadan,* and the pilgrimage to Mecca – are known and practiced throughout the region. Other kinds of popular religion reflect the significant role played by Muslim mystics *(Sufis)* in the conversion process. These include pilgrimage to the tombs of saints, ritual recitation of the *Qur'an,* healing rites, and the celebration of the *maulid* or birthday of the Prophet Muhammad. Sufi orders continue to play significant parts in social, religious, and political life in most Asian Islamicate societies. For many Asian Muslims Sufi devotionalism is more important than that required by Muslim law.

Islamist Movements

Islamist movements advocate the 'purification' of Muslim religious life. In general they seek to restrict devotional acts to those prescribed by Islamic law. They strongly oppose *Sufism* and rituals rooted in or associated with pre-Islamic traditions. They also seek to establish the Islamic law as the basis for social and political life. They are significant voices in intellectual, social, and political discourse throughout Islamicate Asia. Most have intellectual roots in the theology of the nineteenth century Egyptian modernist Muhammad Abduh. They emphasize a combination of modern education and religious zealotry. Many believe that the realization of the goals can be facilitated by the establishment of Islamic states. Support for these movements is found primarily among urban, middle-class movements. They are strongly opposed by traditional religious elites and in most instances ignored by rural populations.

Abstract

More than any other religion, Islam understands itself in relationship to its past, as believers seek to emulate the lives of the Prophet and his associates. This means that the language and culture of Arabia is of critical spiritual import for all Muslims. This article will outline the historical experience of Islam in Arabia, with attention paid to the social circumstances surrounding the rise of Muhammad's prophecy, and to the development of hadith scholarship, jurisprudence, and sectarianism over time within the Arabic Muslim community. The problematic relationship of Islam with the state will be briefly considered in historical perspective, as will the rise of charismatic and millenaristic movements. But what will be stressed is the pragmatic and personal moral message of Islam, and its effect on ordinary Muslims in Arabia.

Islam in Historical Context

Islam claims to be the direct word of the almighty and omniscient God (Allah), as directly revealed to His Messenger, Muhammad. Written down in the Quran, Allah's commands provide Muslims (those who submit) with the final and authoritative pathway to salvation, as well as a code of proper conduct covering all aspects of ordinary life. Islam is arguably the fastest growing of all religions, daily continuing its rapid spread throughout every corner of the world. Yet, despite its cosmopolitan character, Islam remains inextricably linked in language and in character to its past in the desolate heart of Saudi Arabia, where it arose in the beginning of the seventh century AD (for standard histories, see Hodgson, 1974; Lapidus, 1988).

This arid place was an extraordinarily unlikely spot for a new world religion to bloom. In fact, Arabia had avoided conquest by the stronger surrounding powers primarily because of its geographical isolation and physical harshness. The marginalization of Arabia meant that none of the major religions of the surrounding world had gained ascendance there, although the Arabs traced their own genealogical charter back to Ishmael, the son of Abraham and Hagar, and therefore had a historical connection with Judaism and Christianity. But in practice they worshipped a plethora of local gods (who remain powerful today under the guise of *jinns*). These divinities offered their devotees protection from the unpredictable environment and acted as guardians during holy months when clan feuds were set aside and markets were organized on sanctified ground. One of these markets, according to many scholars, was to be found in the central Arabian crossroads of Mecca, site of the kaaba, the holy black stone that is now the goal of the *hajj*, the annual Muslim pilgrimage (for a contrary view, see Crone, 1987).

There is great controversy among Western scholars over the accuracy of Islamic records concerning the early years of the religion (c.f. Crone and Cook, 1977; Humphreys, 1991; Wainsbrough, 1977; Watt, 1973, 1988), but most accept that Muhammad, the Prophet ofIslam, was born in Mecca in approximately the year 570 to a member of the Quraysh clan, the kin group that controlled the market and its gods. As a posthumous child he had to rely on the guardianship of his paternal uncle, Abu Talib, and in his later revelations Muhammad was especially concerned with the protection of widows and orphans. With the help of his first wife, the successful and much older tradeswoman Khadija, he eventually became a well-to-do merchant, much respected for his integrity, good judgment, and fairness by his fellows, who called him al-Amin, the trustworthy.

At the age of 40, during a meditative retirement on Mount Hira, Muhammad was gripped by the first of the uncanny revelations that would eventually be collected into the Quran. In his vision, the angel Gabriel spoke to him, commanding him to 'Proclaim! In the name of thy Lord and Cherisher, who created – created man out of a leech-like clot.' Later revelations occurred at intervals throughout his life. One hundred and fourteen of these revelations, presented in rhymed verse of surpassing beauty and novelty, were definitively collected and collated in sections or *suras* of descending order of length (not chronology) shortly after the Prophet's death. These became the Quran, the central holy text of Islam. For the Arabs, whose major art form is poetry, the extraordinary aesthetic power of the Quranic verses was a convincing proof of their divine source. Oral recitation from the Quran remains today as the most important way for the faithful to experience the sacred (Nelson, 1986).

According to Muslim hagiography, Muhammad's revelations originally had little influence in Mecca. His first converts were Khadija and some of his closest relatives, including Abu Talib's son Ali, who was later to marry Khadija's daughter Fatima. But most of the early believers were those who were poor, disenfranchised, and humble. They were drawn to the Quran's condemnation of excessive riches, to its advocacy of generous donations to care for the disadvantaged, and to its repudiation of the arrogance and selfishness of the wealthy. Yet the Quran also had a place for the interests of the upper strata. According to Muhammad's revelation, wealth and power were not bad in themselves – only greed, arrogance and an absence of community responsibility.

Nonetheless, most of the Meccan populace were unwilling to follow the Islamic demand that they pay *zakat* (a tax to be

redistributed to the community of believers), cease to hoard, participate in community charity, and refuse interest on loans. According to legend, many were especially angered at Islam's absolute denial of the might of their clan gods in favor of the complete domination of Allah – a threat to the basic structure of their patriarchal society. Also galling for them was the Quranic demand that the great show submission by prostrating themselves in prayer to the Almighty God who would judge them on the Last Day.

After the death of his defender and uncle, Muhammad and his followers suffered increasing persecution in Mecca and looked for refuge elsewhere. Eventually, in 622 the Aws and Khazraj tribes of the agricultural oasis of Yathrib (later called Medina), anxious for a leader who could mediate their interminable feuds, begged Muhammad to migrate there. Fearing for his life in Mecca and hopeful of increasing his following, Muhammad accepted this invitation, and undertook the *hijra* to Medina with his followers – an event marked as the beginning of the Muslim calendar. It was there that he built the foundations of his holy empire, attracting converts from the surrounding tribes as he sought to conquer the Meccan confederation that had repudiated him. Following his inspiration, he rallied his following to struggle against the odds, defeating a much larger Meccan army at the battle of Badr in 624, successfully raiding Meccan caravans, and threatening Meccan commercial dominance. Finally in 630 the Muslim army occupied Mecca itself, as Muhammad's Qurayshian cousins were obliged to convert to his cause. When Muhammad died in 632, his followers had conquered the whole Arab peninsula, and had begun their great and ultimately successful war against the surrounding Sasanid and Byzantine empires. All of these events remain in the forefront of Muslim imagination to this day.

The Muslim explosion which burst from the hinterlands of Arabia was historically unparalleled; it united the Middle East into one open trade area, paving the way for the rapid creation of new prosperity. At the same time, the radical Muslim message of the equality of all believers struck a cord with the common people of the empires, who, theoretically at least, were liberated from their inferior status by the simple act of conversion. The rise of Islam was thus both an economic and social revolution, offering new wealth and freedom to the dominions it assimilated under the banner of a universal brotherhood guided by the message of the Prophet of Allah. Of course, in practice the situation was more complex and ambiguous, as Arabs – proud of their early support of Muhammad – claimed superiority over the more recently converted Persians and Berbers, who in response demanded equal rights for themselves under the *sharia* or Muslim law. There was also rivalry between the old Qurayashian elite and the upstarts who had gone into exile with Muhammad, and now claimed special precedence for themselves. Nonetheless, Islam expanded rapidly, and soon predominated throughout the Middle East, from Morrocco to Afghanistan (for accounts, see Bulliet, 1994; Gibb, 1962; Shaban, 1971; Wellhausen, 1927).

In the Muslim imagination this was a period when the 'City of God' was actually realized in historical reality, under the authority of the Prophet himself and the four pious Caliphs after him: Abu Bakr (d. 634), Umar (d. 644), Uthman (d. 656), and his patrilateral parallel cousin Ali (d. 661) – who led Islam in its holy war against the unbelievers. To compare the Muslim experience with Christianity, it is as if Jesus had commanded an army that subdued Jerusalem, and Peter had become Emperor of Rome. Muslim thought is saturated with longing for a return of this idealized era when ordinary men and women worked together selflessly to realize the will of Allah under the leadership of just and divinely guided leaders, and were rewarded for their efforts by vast power and wealth.

Recalling their millennial past, the Muslim devout, unlike their Christian cousins, have never inwardly consented to the disjuncture between the religious experience of the community of believers (equal before God, led by the Prophet and his deputies) and the later reality of power-seeking secular rulers given to political intrigue and physical coercion. The remembered unity of politics and religion during the first years of Islam has always remained available as an inspiration to Muslim reformers and as a rebuke to politicians. That unity is evoked today by Muslim reformers, who inevitably decry the corruption of the times and call for a return to the pure faith and practice of the past (for an example, see Mitchell, 1969).

To a great degree, the extraordinary victories achieved by early Islam were a result of the manner in which Muhammad's message transformed and expanded the worldview of the tribesmen who became fighters for the faith. As in a tribe, within the Muslim community – the *umma* – co-responsibility was required, and all believers were strictly prohibited from exploiting, injuring, or enslaving one another; they were obliged as well to share their resources through charitable contributions redistributed to the community at large. They were also expected to unite together in holy war (*jihad*) against the enemies of the faith. Joining the *umma* was a voluntary matter, but once the faith was accepted then a Muslim was forever committed, just as a tribesman was forever linked to his kin.

Also ratified and transformed by Islam were the mercantile values Muhammad had grown up with in Mecca. The Quran does not repudiate commerce, nor did the growth of Islam destroy trade and markets. On the contrary, Muhammad's message favored entrepreneurship, and integrated the ethics of the merchant into Islamic virtue. Profit, if fairly made and appropriately spent in the service of God and to help the deprived, is praised in the Quran, while the absolute right of individuals to own and dispose of personal property is assumed, as is the right to make contracts. In fact, the Quran is permeated with the imagery of the marketplace, which must have appealed directly to the individualistic mercantile values of the people of the time, both urban and rural, who were all so dependent on trade for their livelihoods (Rodinson, 1973; Torry, 1892).

Most importantly, the Quran emphasized the spiritual equivalence of all persons, who are held to be responsible for their own destinies and who will be judged as individuals by Allah on the Last Day. In principle, Islam is the least hierarchical of all religions: there are no priests, no church, no monks, no difference between clergy and laymen. Everyone is alike in the eyes of the transcendent and absolute God to whom all must submit. This aspect of Islam applied even to the Prophet, who was at pains to deny any sacred or superhuman status to himself. When doubters asked Muhammad to verify his revelation by miracles, he replied that the miracle of the

Quran was sufficient, and that he was but an ordinary man, who had been singled out by God as the messenger of His word. In its egalitarianism and individualism, Islam accurately reproduced the dominant mores of its tribal and mercantile Arabian environment (Lindholm, 1996).

Yet Muhammad's community, though it reflected the surrounding culture, was also something completely different than had existed previously. In their own imagination of themselves, the early Muslims were not yet another tribal grouping gathered around a sacred marketplace; they belonged to the 'party of God' – opponents were infidels. Nor was Muhammad one judge among many; he was the ultimate and final authority over a millenaristic nativist movement that aimed at nothing less than transformation of the world. Despite his protestations, for his followers Muhammad was not like everyone else; he was the perfect man who had actually seen the face of God (an event celebrated throughout the Muslim world).

In its prophecy, Islam followed in the tradition of the Middle Eastern exemplary religions already proclaimed by Moses, Jesus, and Zoroaster, who had all called for believers to submit to the moral codes imposed by an all-powerful yet personalized God: for them, faith and deeds, not heredity and power, were the true measure of spiritual enlightenment; the ethical action of individuals in this world was a prerequisite for passage into paradise (see Weber, 1978 on the nature of exemplary prophecy). Far from wishing to repudiate his predecessors, Muhammad believed his mission as 'the seal of the Prophets' was to correct and complete these earlier revelations, which had been misinterpreted and garbled. Because Muslims believe that the Quran preserves God's direct words in a pristine state, most are extremely reluctant to apply modern Western methods of textual criticism to the holy book.

The Rise of Shi' ism

While Muhammad lived, the *umma* was united under his charismatic leadership, but after his death, it inevitably began to lose its moral cohesion. Rebellions and internal schism rent the community, and after the death of Ali in 661 the realm of Islam was plunged into a cycle of tyrannical rulers and foreign invasions, punctuated by intermittent religiously inspired insurrections. Ali's own son, Husain, led one such revolt, but was pitilessly slaughtered in the battle of Karbela in 680 – an event re-enacted and mourned today in the great self-lacerating celebrations of Muharram held among Shi' ites – the 'partisans' of Ali – who are the largest sectarian group in the Middle East (Chelkowski, 1979). Today Shi' ites of different types compose nearly all the population of Iran, over 50 percent of the population of Iraq, 70 percent of Bahrain, and one-third of the populace of Lebanon. Altogether, the Shi'ites are estimated to make up 11 percent of all Muslims.

Ever since Husain's martyrdom, uprisings against the corruption of the faith have periodically been undertaken in the name of Ali and his descendants, who were believed by their partisans to be the legitimate inheritors of Muhammad's sacred authority. By restoring Ali's line to the throne, the schismatics hoped to re-establish the realm of God on earth. Usually, these movements fell victim to repression by powerful rulers, and they also suffered from internal disorganization, as there was disagreement over which of the possible claimants deserved the title of the Imam – the divinely appointed ruler. Even when successful, Ali's partisans suffered from problems of maintaining a sacred polity over several generations. For example, the great Fatimid dynasty of Egypt (969–1171) disintegrated over issues of succession, as one Imam denied his own divinity, while a later one had no sons (for a short history of Shi'ite, see Richard, 1995).

The most successful Shi'ite strategy was followed by the so-called twelvers, who presently dominate in Iran. After their eleventh Imam died without issue, it was argued that the next Imam was actually living in occlusion, and would not return until the final judgement, though he could sometimes be contacted in dreams and visions. This sect then developed a complex and rigorous educational system that aimed to produce religious scholars capable of both interpreting sacred texts and of attaining mystical communion with the hidden Imam. Such men, acclaimed by their fellows for their special spiritual gifts, became exemplary figures in themselves, and were recognized as *ayatollahs*, 'miraculous signs of God.' Every *ayatollah* had his own loyal disciples, as well as access to endowments and to donations from followers; most importantly, each retained the right to independent judgment. Only with the political ascendance of Ayatollah Khomeini in the 1979 revolution was this pluralistic system overthrown, and a new centralized spiritual authority inaugurated by the state, which proclaimed itself to be the final arbiter of truth. The future of this experiment remains to be seen, but it must be noted that it flies in the face of twelver Shi'ite tradition (Arjomand, 1988).

Sufism: The Mystical Path

A second reaction to the disintegration of the Caliphate was Sufism: so called, it is said, because practitioners wore rough woolen robes to indicate their unworldliness. Like the Shi'ites, Sufis also hoped for a renewal of the faith, but for them this could only be accomplished by a spiritual return to what they believed were the original practices ofIslam. The more ardent of them withdrew into the wilderness where they practiced severe austerities in pursuit of an immediate experience of the divine. Many devoted themselves to repetition of devotional phrases (*dhikr*) which were combined with special breathing patterns and rhythmic movement to induce spiritual illumination (Arberry, 1950; Schimmel, 1975).

By the twelfth century, the Sufi pursuit of enlightenment had become institutionalized, as saintly figures (often called *shaikhs*) founded various lodges *(tariqas)* where they taught followers their own mystical practices. Students *(murids)* were immersed in a community of brothers detached from the ordinary world, obedient to the will of their spiritual guide, who alone could provide the blue patched 'frock of blessing' and dervish cap to pupils judged to have achieved a measure of divine grace. These newly enlightened individuals could then act as spiritual guides to their own pupils, adding to the *silsila*, or chain of knowledge, reaching back to the original teacher. While the Shi'ites argued for a hidden Imam, the Sufis claimed there was a *qutb*, a pivot of the universe, a perfect man veiled from ordinary men, to be discerned only by the spiritual elite, who themselves were organized in a secret hierarchical order of

the 'friends of God,' manifested on the local level in the *tariqas* (Trimingham, 1971).

Sufism had great influence throughout the premodern Middle East, and throughout the Muslim world, as wandering mystics furnished a cohesive vision of the cosmos in the face of a splintering polity while simultaneously providing new converts with an experiential religion suitable for an unsophisticated audience. Establishing their lodges in the hinterlands around the tombs of saints, Sufis regularly served as the mediators in local tribal disputes and as guardians of the peace, gaining disciples and considerable power – so much so that they could occasionally become leaders in revolts, uniting tribes against the state (Gellner, 1981). The greatest historical example were the Safavids, who originated as followers of a Sufi saint, and who ruled Persia from 1501 to 1722. Sufism also found a receptive audience in the cities, where the ranked organizations of worker's guilds and local clubs paralleled the hierarchical order of the *tariqas*. Military groups too found the Sufi message to their taste, while intellectuals and scholars were attracted to the controlled 'sober' forms of Sufism, so much so that it was quite common for an orthodox Muslim cleric to be a Sufi adept as well – the best known example being al-Ghazali (d.1111) (Watt, 1953). In contrast, radical 'drunken' forms of Sufi worship appealed to the impoverished and sensation-seeking urban masses, who could lose themselves in ecstatic performances of *dhikr* (see Massignon, 1982).

Sufism spread with Islam to the rest of the Muslim world, where it still is a powerful spiritual force. However, in the modern Middle East, Sufism has more or less lost its significance. It only remains powerful in Turkey, where the complete assimilation of orthodox Islam into the Ottoman state meant a repudiation of orthodoxy when that state lost legitimacy, leaving Sufism as the major alternative to secularism. Elsewhere, the oppositional role traditionally played by Sufism has been taken over by various fundamentalist groups which loudly accuse Sufis of being anti-Islamic saint worshippers. Yet, like Sufi *tariqas*, these groups too are founded by zealous individuals who believe they have direct access to a purer faith, and who demand the absolute and self-abnegating loyalty of a cadre of followers. The Sufic social structure thus lives on, even though its mystical content has been denied (Roy, 1994).

Islam in Theory and Practice

While there has always been a powerful impulse in Middle Eastern Islam toward charismatic leadership, for the vast majority of Muslims the Quran remains the primal source of spiritual knowledge. Ideally there should be no need at all for human leadership when God has sent down rules to regulate and evaluate all human actions; rules which can be discovered by anyone who can read the holy text. But the Quran, being finite, does not and cannot explicitly cover all circumstances. There are many areas of behavior left out, some questions are not answered, other precepts are ambiguous, and sometimes there are contradictions or apparent impossibilities in the text.

In the face of these difficulties, some early Islamic thinkers (Mutazilites), influenced by Greek thought, attempted to force the Quran to conform to reason, but this effort was defeated in the ninth century by the 'traditionalists' led by the great theologian Ibn Hanbal (d. 855), who argued that the omnipotence of God meant that any constraints on Him and on His word – even the constraints of reason – were a form of idolatry. This did not mean that reason was banished – in fact, the use of analytic argument flourished in Muslim scholarship – but reason was firmly limited to explication of the legal implications of the sacred text; it could not be extended to put limits on God.

In place of an explanatory theology that attempted to unite logic and religion, Islam concerned itself with the obligations and prohibitions commanded by Allah: individual devotional practice and acceptance of the Word are what is crucial, not reflection or rationalization. In its emphasis on application, Islam has been appropriately described as a religion not so much of orthodoxy as of orthopraxy, reliant on ritual actions to reveal and inculcate faith (Smith, 1957). The very word 'Islam' signifies an act – the initiatory act of surrender and submission to God. The essential practices required of all Muslims are five: the public profession of the faith (God is one, and Muhammad is his Prophet – recitation of this is sufficient for conversion), five daily prayers, the pilgrimage to Mecca for those who are able, donation of *zakat*, and the month-long fast of Ramadan. Some Muslims now say holy war should also be seen as compulsory, but this is a matter of controversy, and in any case can be interpreted as a struggle against one's own base instincts.

In all instances, these shared practices are simple, direct, and spiritually compelling. The aim of each is to infuse the faithful with the necessity of a willed subordination of the self to the dictates of the overarching Muslim community while offering in return both the promise of reward in the afterlife and immediate compensation in the here and now. The human rhythm of Muslim practice is clearest in the fast of Ramadan, which is the ninth month of the Islamic lunar calendar. During this period it is strictly forbidden to eat, drink, smoke, or have sexual contact. However, fasting is not regarded by Muslims as a way of atoning for sins through suffering, as it is in the Judeo-Christian tradition. Rather, all restrictions are lifted as soon as the sun sets, so that a greater quantity of food is eaten during the evenings of Ramadan than during the rest of the year, and the meals are of higher quality. Ramadan feasts also involve celebratory gatherings of friends and family, and a public redistribution of alms and food to the needy.

The rhythm of constraint and release, solitude and community, culminates in the great Muslim festival of *Eid al-fatr* – literally the lesser festival, but in actuality the major celebration of the year (*Eid al-attar*, the 'greater festival,' is a re-enactment of Abrahamic sacrifice in which a sheep is slaughtered and shared out with family, dependents and the poor). *Eid al-fatr* is very much an affirmation of participation and renewal, as Muslims everywhere put on new clothes, visit, embrace, share food and drink, and gather for prayer. Forgiveness of all insults and enmity is mandated; debts are canceled and old enemies embrace to show their renewed brotherhood. The music and celebrations that marked the whole month are intensified, and the tombs of the ancestors are visited, reaffirming again the continuity of the community with its sacred past. High and low are leveled through the giving of alms; sharing in hunger gives the wealthy a sense of the contingency of their plenty and brotherhood with the

impoverished, who, like all other Muslims, take part in both the fast and the feast. The egalitarian and individualist message of Islam is reaffirmed through action, as salvation is achieved by the deeds of individuals in this world, who unite with their fellows in the performance of socially and spiritually rewarding acts of self-sacrifice.

Within this theology of practice there is no original sin. Mankind has been placed on the pathway and given directions, he only needs to heed and obey. The Quran is a light to guide travelers as they work their way through the darkness of earthly life toward the climactic moment of the final judgment. Redemption, atonement, an irredeemable inner sense of evil – these aspects of Christian dogma are left aside in Islam where the punishment for turning away from the path is simple and terrible – God withdraws Himself, and leaves the individual alone to wander without a guide in the moral wilderness, destined never to reach paradise.

Yet despite the absence of original sin and the emphasis on practice, Islam is not a religion of positive thinking. Election to the ranks of the saved cannot be assumed to follow from proper practice or good works; salvation is solely a consequence of God's ineffable and unpredictable grace. Fear of the utter power and unknowability of God is mitigated only by reliance on His positive qualities. In the Quran Allah has continually described Himself as merciful and compassionate, and Muslims hope for His forgiveness. Notwithstanding God's compassion, the impossibility of pleasing an utterly transcendent, unpredictable, and indeterminable Deity necessarily leaves Muslims in a state of trepidation and perplexity as to the state of their souls.

The Primacy of Memory

In their effort to please God, and fearing their own all-too-human fallibility and hypocrisy, Muslims have naturally sought other means to secure salvation beyond the study of the Quran and following its precepts. In particular, they have tried to emulate the actual practices of Muhammad and his followers (*Sunna* – the 'trodden path'), reasoning that these must serve as the most reliable template for behavior approved by Allah. As a result, Islam, more than any other religion, has always been preoccupied with discovering, preserving, and imitating its own past. Such historical memories serve, with the Quran, as the major source for Muslim moral consciousness.

So it is that where other religions interpret their holy texts through the decisions of authoritative legislative bodies, or through deduction from general principles, Muslims instead discovered principles and authority through the collection of historical records of the words and deeds of the founder and his companions. This was the task of the preservers of reported history or, as they are conventionally known, the *ahl al-hadith*, people of 'tradition,' who at first were simply individuals who had lived in the original *umma*, and could report on its practices.

Over the generations, reciters became professionals who concentrated on developing their memories and eliminating personal biases so they could repeat, verbatim, what they had heard from those before them, without interpretation, comment, elaboration, or condensation. They also had to be moral exemplars, since *hadith* were judged reliable not only on the basis of historical criterion, but also on the basis of the integrity of the reciter. Those approved could then enter into the *isnad*, or 'chain' of reliable transmitters that was recited whenever the tradition was spoken. As Islam spread, the traditions were codified, validated, and published in six so-called 'canonical' collections, which served, with the Quran, as the basis for legal decisions.

Legalism and the Problem of Interpretation

The jurists (*faqih*) who interpreted the sacred texts at first overlapped almost completely with the *ahl al-hadith*. Neither had any formal education, and both were devoted to the study of the Quran, the *sunna*, and the traditions. The difference was that the lawyers developed regulations for matters left unclear by scripture, such as the exact nature of a property transfer. They also had to clarify the weight of any particular rule: was a practice obligatory, merely recommended, or neutral; if obligatory, should failure be punished by men, or left to the discretion of Allah?

However, from the point of view of the traditionalists, the jurists' use of reason and analogy to fill in lacunae or resolve apparent contradictions in the holy texts was frivolity at best, idolatry at worst. The potentially disastrous dispute between literalists and interpretivists was classically resolved by the theologian al-Shafi (d. 820), who argued that *ijma*, the agreement of knowledgeable scholars, ratified by the community itself, decides the manner in which ambiguities in sacred texts are to be understood. In other words, Islamic theological disputes ought to be decided democratically, by consensus – albeit a consensus arrived at over generations.

This consensus is never final, since an authoritative dissent can, in principle, cause a reopening of the debate if that dissent manages to gain scholarly sanction and public endorsement. Shafi's compromise retained the egalitarian and populist character of Islam while simultaneously recognizing the importance of expert legal knowledge as the arbiter of tradition. Continuity through collective consensus still permitted the theoretical possibility for new interpretation – a possibility that continues to be the source of intense debate among contemporary Muslims.

Two centuries after Shafi's reforms the legal schools or *madhhab* (literally a 'chosen way') were whittled down to four, each named after its supposed founder: al-Shafi, Ibn-Hanbal, Malik b. Anas (d. 795), and Abu-Hanifah (d. 767), and each teaching its version of the law in specialized colleges (*madrasas*), and producing scholar-judges (*ulema* – people of knowledge). After some violent wrangling, it was eventually accepted that the schools should be considered equally accurate in their interpretations of divine law, since 'only God knows' the truth (Makdisi, 1981). Though ideally one could choose any school to follow, most Muslims accepted the *madhhab* prevalent in their area. The central Middle East remains Hanafite or Shafite, the Malikites prevail in North Africa, while the Hanbalite school remains fairly small, but is intellectually influential. Shi'ites too have their own legal schools, slightly variant from those of the Sunnis – in fact, the first college in the world, al-Azhar in Cairo, was founded in 970 by the Shi'ite Fatimids.

Even today, despite public efforts at rationalization, Islamic law has remained remarkably personalized and open to interpretation, since there is still no central ecclesiastical organization enforcing rules, nor any standard procedure for appeal to

a higher ecclesiastical court (indeed, there is no hierarchy of courts whatsoever). For these reasons, different juristconsults can issue *fatwas* (legal opinions) at odds with one another – much to the confusion of Western observers (Coulson, 1964; Goldziher, 1981).

Muslim Resistance to the State

Efforts by Middle Eastern states to incorporate, rationalize, and secularize Islamic law have always met with ambiguous results, as the majority of Muslims remain suspicious of the motives of secular authorities. For a recent example, when al-Azhar was completely integrated into the Egyptian state in 1961, its graduates were increasingly seen as minions of the government. In response, many self-taught Muslims have opened their own local schools for the training of religious scholars (Gaffney, 1994). Similar patterns have occurred elsewhere in the Middle East, where popular mistrust of the official *ulema* has periodically led laymen and reformers to try to find a pathway to a purer and more egalitarian form of Islam.

This is so much the case today that, except in Iran, those offering an 'Islamist' critique of the state are usually autodidacts self-consciously distancing themselves from the class of the traditionally religiously educated, who are tainted by their graduation from state schools. But although ordinary Muslims are suspicious of the state, they are equally distrustful of those zealots who say they have privileged access to the truth. The best course, they believe, is to avoid conflict with the secular authorities, submit to the precepts of the Quran, *sunna,* and *hadith,* and rely on Allah's infinite mercy.

Abstract

Nigeria's Muslim population, generally estimated to be over 50 million, is the largest in this part of Africa, and the focus in this article is on the growth and impact of Islam there, and in East Africa, especially in Tanzania. Broadly speaking, there have been three stages in the development of Islam in tropical Africa: quarantine, mixing, and reform. In the first of these stages Muslims, mainly merchants from North Africa, tended to live in closely knit communities and apart from the indigenous population. The second stage was characterized by the mixing of Muslim and traditional beliefs and rituals, a process which gave rise to the third stage, that of reform. The article is particularly concerned with the role of the scholar-mystic as reformer and nationalist and the impact of colonialism and Islam in the context of the post-independence nation-state.

An estimated 140 million Muslims live in tropical Africa, also referred to as sub-Saharan and Black Africa. The majority are concentrated in the Sahelian and Savannah regions that lie to the south of the Sahara proper, between the Atlantic to the west and the Red Sea to the east, in the Horn of Africa and along the East African coast from Somalia to the northern region of Mozambique. Nigeria's Muslim population, generally estimated to be over 50 million, is the largest in this part of Africa, and the focus in this article will be on the growth and impact of Islam there, and in East Africa, especially in Tanzania where, as in Nigeria, there is also a heavy concentration of Christians, a situation that affects the character, policies, and objectives of both religions in both countries. Elsewhere either Muslims or Christians are in a clear majority.

The advance of Islam and Christianity throughout tropical Africa has not undermined all traditional beliefs and rituals. On the contrary, as modernization has brought new challenges to community and personal life, people have not rejected the traditional belief systems for the 'newer' religions but have tended to juxtapose – the term syncretize is misleading – them, and to have recourse to either one or the other depending on the concerns that require a spiritual solution.

Broadly speaking, there have been three stages in the development of Islam in tropical Africa: quarantine, mixing, and reform. In the first of these stages Muslims, mainly merchants from North Africa, tended to live in closely knit communities and apart from the indigenous population. The second stage was characterized by the mixing of Muslim and traditional beliefs and rituals, a process which gave rise to the third stage, that of reform.

West Africa Until the Nineteenth Century

It was through commerce that, over 1000 years ago, Islam began to spread to West Africa and indeed to most of tropical Africa. During the eighth century, Muslim merchants of both Arab and Berber origins began to work their way across the trans-Saharan trade routes to the Ancient kingdoms of Ghana and Kanem Borno situated within the frontiers of what is today western Africa.

After gradually establishing itself as the religion of court and commerce, Islam came to be seen as a progressive, modernizing force in Tropical Africa. The traveler Ibn Battuta (1304-68/77) left an account of the healthy condition of Islam in Mali in the middle years of the fourteenth century. He was impressed by the meticulous observance of the Friday prayers, the importance attached to the learning of the *Qur'an* by heart and the fidelity with which *zakat* or almsgiving was practiced. Ibn Battuta also pointed to what has been a feature of Islam in West Africa since its beginnings there: mixing. He noted the retention in Muslim circles of traditional religious customs, including divination, prostration before a ruler, and the matrilineal system of inheritance, considered to be contrary to Islam, and given by reformers as the principal reason for *jihad*.

Early on Islam encountered Christianity in tropical Africa. By the middle of the seventh century, Arab Muslim traders had come into contact with the Christian kingdom of Nubia which, when unified, stretched from the second to the sixth cataract of the Nile, although there was little by way of Islamization until the arrival of the Mamluk dynasty in Egypt in the second half of the thirteenth century. A combination of military pressure from Egypt and royal marriages between the Egyptian and Nubian dynasties resulted in the establishment of Muslim rule in the capital of the Nubian state of Muqurra in the first half of the fourteenth century.

The Scholar-Mystic as Reformer and Nationalist

While Islam in tropical Africa has been spread largely by peaceful means and has used the same means to reform itself, the launching of the Almoravid movement in the southern sector of the Sahara in 1054 by Abdullah b. Yasin initiated a tradition of militant reform that was to influence the course of West African Islam down the centuries, inspiring future *jihads* or holy wars.

In the fifteenth century, this tradition was given intellectual and doctrinal weight by the Muslim scholar Al-Maghili (1425–1502) from Tlemcen in southern Algeria, who spent many years teaching Islam and counseling rulers in Hausaland (present day northern Nigeria) and the central Sudanic kingdom of Songhay (present day Niger). His radical teachings on the Shari'a (Islamic law), Muslim government and education, gender and taxation were communicated in reform manifestos to scholars and rulers across the western Sudan.

The seventeenth century saw the beginnings of a series of *jihads* in western Africa culminating in the Sokoto *jihad* which was to change the cultural and religious landscape of that region during the first half of the nineteenth century. It was launched by the scholar and mystic from the hinterland of Hausaland in northern Nigerian, Shaykh Uthman dan Fodio (1754–1817) early on in the thirteenth century of the Muslim *hijra* (1785–1882) – the century which, it was widely believed, would witness the advent of the Mahdi (God-guided one) who would ensure the triumph of Islam everywhere. The principal target of this jihad, one of the most thoroughgoing in the history of Islam, were the nominally Muslim urban based government administrators and the jurists who were accused of every kind of corruption and oppression. Oppression of fellow Muslims, Shaykh Uthman preached, was tantamount to infidelity on the ground that a believer was duty bound to befriend a fellow believer.

The Madhi, many were convinced, had arrived in the eastern Sudan in 1881 in the person of Muhammad Ahmad. A member of the puritannical *Sammaniyya* Sufi order, Muhammad Ahmad, in a brief period, overthrew Egyptian rule in the Sudan and established an Islamic state there which lasted until 1898. Like that of Shaykh Uthman dan Fodio, the Sudanese Mahdi's religious nationalist movement was both rural based and directed against the corrupt urban based elites, mostly Turco-Egyptian officials. The careers of both men highlight the crucial role of the mystic as reformer in African Islam.

After the Madhi the Sudan was to become, in theory, a condominium under joint British and Egyptian rule until 1952. The Sudan has suffered from a civil war between the largely Muslim North and the Christian, traditionalist South since 1955. Since that time several administrations have been engaged in extending Islamic law and education across the South.

Islam on the East African Coast Until the Nineteenth Century

As in West Africa, Islam's early development on the East Coast was slow. It spread more easily and evenly among the nomadic and seminomadic populations of Somalia and the Horn generally, while further south it remained confined to many of the island populations including those of Lamu, Pate, Pemba, Comoros, Mombasa, and Zanzibar, and to a few settlements on the coast itself. The best documented of the early coastal settlements is Kilwa, founded by Shirazi immigrants from the Arabian peninsula in either the tenth century or in the twelfth century. Though early Islam was largely confined to the coast Arab immigrants had established a Muslim state far inland in Shoa in Ethiopia by the ninth century which was later absorbed by Ifat, one of seven Muslim kingdoms all tributaries of Christian Ethiopia.

By the first half of the fourteenth century a well-developed Muslim society had been established on parts of the coast of East Africa. Once again Ibn Battuta, the chronicler and traveler, who visited Mogadishu in Somalia in 1331, provides a picture of the state of Islam at the royal palace at this time. He describes a deeply Islamized court around the Arabic speaking ruler and/or shaykh who was assisted by a Muslim judge or *qadi* from Egypt. Furthermore, East African students had already begun to travel to study in the Islamic university of Al-Azhar in Egypt, a tradition begun in West Africa much earlier.

Though historically less militant than western African or Sudanese Islam, the fusion of Islam with local coastal customs and traditions created the context for reformers to engage in *jihad* or holy war. The reformer Ahmad b. Ibrahim (1506–43), better known as Ahmad Gran, waged several *jihads* from the Muslim state of Adal, situated in the interior, into the Christian kingdom of Ethiopia which involved not only the purification of Islam but also the conversion of Christians. Paradoxically, the indirect consequence of those *jihads* was the disintegration of the largely Muslim region of Adal, the main area of relatively settled Islamic life in the interior, although Harar, to the south, remained for Somalis a center of Muslim orthodoxy. In the second half of the sixteenth century the Galla, originally from south central Ethiopia, began to expand and by the nineteenth century a number of ethnic groups further north including the Wallo were largely Muslim.

Though Islam made little further progress in the East African interior until the nineteenth century, Arab Muslim culture had begun to interact with the indigenous Bantu cultures through marriage and concubinage to produce the new and distinctive culture known as Swahili, an Arabized-Bantu lingua franca spoken in Kenya, Tanzania, and in the eastern sector of the Democratic Republic of the Congo. The Muslim presence on the coast, on the other hand, was strengthened by the arrival of the Ottomans who occupied Masawa in 1557, and came into conflict with the Portuguese who had burnt down Zayla' in 1517.

East African Islam Turns Inland

The Yao people, situated midway between Lake Nyasa and the Indian Ocean and part of a trading network that included slave trading stretching from the Indian Ocean west to Katanga, were the only major ethnic group south of Somalia to turn Muslim prior to the nineteenth century. During the first half of that century increasing economic expansion inland began to effect a profound reorientation in outlook, attitude, and priorities among the Muslims of the coastal settlements. Muslim traders and agriculturalists began to move into the interior to Tabora, Ujiji, Nyangwe, Buganda, Lake Nyasa, Katanga, and elsewhere, and while not actively proselytizing they were, nonetheless, spreading Islamic culture by imitation.

The first Muslims arrived in Buganda, part of present day Uganda, from Zanzibar in the mid-nineteenth century during the reign of Kabaka Suna. Arab influence increased in the 1860s under Suna's successor Mutesa, not a full Muslim himself (he was not, for example, circumcised) and this was manifest in Buganda's adoption of the Islamic calendar, the observance of Ramadan, and the wearing of Arab dress which had become fashionable.

Tension created by the uneasy relationship between the demands of Islam and local custom and culture was never far below the surface and erupted in violence as protests by strict, orthodox Muslim visitors to Buganda against Mutesa's leading of the Friday prayers led to a backlash in which 100 Muslims were massacred. The situation was further complicated by the arrival of Christian missionaries in Buganda in 1877. Though in 1888 Christians and Muslims united to expel Mutesa's successor Mwanga, too much a pagan for either, unity soon turned to

hostility as the Muslims expelled the Christians and installed Kalema as Kabaka. A civil war followed and by 1890 the Christians had gained the upper hand and were to receive the backing of the colonial regime. By the treatises of 1890 and 1892, Captain, later Lord, Lugard, acting in the name of the Imperial British East African Company, allocated Bugandan landed chieftainships along religious lines in favor of Christians and this was confirmed by the Ugandan Agreement of 1900. Christianity's dominance in Uganda had been institutionalized.

Colonialism and Islam

Muslim resistance to colonialism has been mentioned in the case of the Sudan and Muslim opposition, both passive and militant, emerged in many other parts of tropical Africa including the Senegambia, Somalia, and Northern Nigeria.

While profoundly disturbing culturally, psychologically, and spiritually everywhere in tropical Africa, the indirect consequences of colonial rule on the actual spread and institutional development of Islam were uneven both in time and place and depending on colonial aims, interests, rivalries, and manpower requirements. At first the German use of Muslims for administrative purposes in East Africa contributed to Islam's progress in the interior, while later this same practice worked against its advance by dividing government personnel from the indigenous peoples opposed to foreign domination. The strongest opposition to German colonial rule came in the form of the Maji-Maji (*maji* in Swahili means water) rebellion (1905–07), organized by Kinjikitile, once again a Sufi or Muslim mystic.

British colonialism which replaced the German system after World War I tended to slow the progress of Islam in Tanzania and elsewhere in East Africa. The system of Indirect Rule at the level of local government tended to protect the power of the local chiefs from being undermined by wealthy Muslim merchants from the coast. Moreover, Christian schools became the main supply of local administrators, teachers, police, and army personnel. The perception was formed of Christianity as the religion of progress, while Islam, as it was gradually sidelined, came to be seen as an obstacle to advancement in the modern sector of the economy and politics.

By contrast with East Africa, British colonial rule in Northern Nigeria relied heavily on Muslim personnel to implement the system of Indirect Rule and even extended Muslim authority to cover the so called 'pagan areas' such as the Jos Plateau. Muslim courts and schools were improved and, as in the Sudan, Colleges of Islamic Law were opened. What mostly assisted the spread of Islam during the colonial era was the improvement in communications, while what mostly disadvantaged Islam and assisted Christianity was the growing importance of western education.

Postindependence Islam in the Context of the Nation State

The independence struggle and the regaining of independence itself provided Muslims, previously under represented in the modern sector of political life and in the civil service in many parts of Tropical Africa, with the opportunity to insert themselves in a more positive and sometimes aggressive manner into the political affairs of the new nation state.

Since independence in 1963, Nigerian Muslims have created a nationwide network of Islamic institutions and have supported the territorial integrity of the federation when threatened by seccessionist movements which continue to exist and the most serious of which, in recent times, came from the eastern region and resulted in the Biafran Civil War (1967–70). On the other hand, in the late 1970s as the country prepared to return to civilian rule after more than a decade of military rule, Muslim members of the Constituent Assembly appointed to approve the Constitution of the Second Republic became embroiled in a serious controversy over the establishment of a Supreme Shari'a Court at the Federal level that threatened the unity of the nation. Many Nigerians not only resented and felt threatened by the Muslim demand for a Federal Shari'a Court but also by the Muslim call for the removal from the preamble to the 1978 draft of the Constitution of the Second Republic the term 'secular state' on the grounds that it promoted secularism, atheism, and immorality. Those skeptical of northern Muslim intentions and more favorable, if not to seccession, then to greater regional autonomy, claim that Muslim enthusiasm for a strong central government reflects a concern not with harmony and unity but over the resources of the country, principally oil, which are located in the South.

Evident in tropical Africa since the 1970s is not only the greater role of Islam in the affairs of the nation state but also the steady increase in Muslims in what were traditionally non-Muslim areas such as Meru country in Central Kenya. The precise number of Muslims in Kenya is unknown but the best estimate would seem to be somewhere between 10 and 20 percent of the population. Islam is also expanding among the black population in South Africa where it was first introduced by slaves and political prisoners from the Dutch East Indies, Madagascar, and West Africa in the late seventeenth to early eighteenth century. Numbers were boosted by the influx of Muslim traders, many of them from Bombay, who distinguished themselves from the indentured laborers from India, a majority of whom were Hindu, who began arriving from 1860.

In the 1980s Muslims joined with Christians of all denominations, Jews, and Hindus in South Africa against the enforced pluralism of apartheid. Today most of South Africa's major cities have a sizeable Muslim presence, and increasing attention is given to education, community integration, and links with the wider Muslim world in Africa and beyond from which it was largely cut off during the apartheid era.

Conclusions

It is usual to stress the fit between Muslim culture and the African condition, and while there was, and is, undoubtedly much common ground between the two, Islam, like Christianity, has been both a destructive and creative force. It has produced many distinguished scholars, mystics, and philanthropists, among them a Muslim William Wilberforce in the person of Shaykh Uthman dan Fodio (1754–1817) of Hausaland in present day northern Nigeria whose writings and program of reform continue to influence and motivate contemporary Muslims not only in Africa but also in the United States and Europe.

Islam has been a major agent of globalization in tropical Africa. Wherever it has settled it has brought numeracy and literacy in Arabic and turned what were regional and/or national trading and commercial networks into international ones. It has also introduced new forms of religious community and spirituality in the form of the *turuq* or Sufi brotherhoods that link believers in tropical Africa to those in the wider Muslim world.

Whether Islam, or for that matter Christianity, has been an innovator or simply a catalyst, where the introduction of such core beliefs as belief in the Supreme Being as totally unique and independent is concerned, is both a fascinating and much debated point among social scientists and historians of religion, but one which space prevents us from discussing here.

Islamic Fundamentalism

Abstract

Islamic fundamentalism came into being as a sociopolitical movement in the twentieth century. It was largely a reactive ideology that was directed against what it deemed to be the complete secularization of states and societies. Such an outcome was related to a variety of systems and worldviews, ranging from democracy and nationalism to socialism and liberalism. Consequently, it perceived Islam as the main victim of this relentless onslaught, whereby its principles, regulations, and strict code of Shari'a law were no longer observed or adhered to, even in Muslim societies. Such a state of affairs called therefore for the establishment of a new revolutionary organization, espousing Jihad as its method of struggle and fully committed to rebuilding a totalitarian Islamist state.

Islamic fundamentalism is a political and ideological phenomenon of the twentieth century. Born in the 1920s, it gathered momentum under the impact of social, political, cultural, and economic changes in Muslim lands in the last quarter of the twentieth century. Taking its cue from movements of Muslim Reform at the end of the nineteenth century, Islamic fundamentalism dented and finally rejected the apologetic modernism of Muslim Reform, while appealing to a return to Muslim origins as announced in the Koran.

Islamic fundamentalism projected an imagined golden age as a social project to be copied in the present, married this to populism typical of the twentieth century, and propagated an antimodernist social and cultural program for resocialization. These included separating men and women in public spaces, turning the veil in its extreme form into a religious duty, and forming vigilante-armed groups to enforce Islamic rituals and obligations. It rested in its moderate forms on social conservatism, but its radical tendencies borrowed ideas of revolution and total societal transformation. It is a movement of varying incidence and depth in Muslim lands and among Muslim Diasporas, with particular appeal to the subaltern intelligentsia and to structurally marginalized sectors of the population, both of whom regard the socially expansive definition of religion a solution to a variety of crises and historical impasses.

Islamic fundamentalism grew among sections of Muslim peoples worldwide in the twentieth century. It is not a unitary and coherent movement but represents a constellation of political, social, ideological, and intellectual trends with varying orientations and national settings.

General Features

Islamic fundamentalism is too much a product of modern history to admit to being regarded, as is often the case, as *sui generis*. It is much too severed from Muslim learned and popular traditions over centuries to admit to being considered, as is habitually presumed, an authentic, albeit condensed, resultant of these traditions. Insofar as it represents the political expression of a particular attitude toward scriptural material, it is a phenomenon generically belonging to the history of religions, with distinctive affinities to the other monotheistic fundamentalisms, Judaism, and Christianity, as well as to other fundamentalisms that are recasting themselves along monotheistic patterns, namely Buddhism, especially in Sri Lanka, and to a lesser extent Hinduism. Insofar as this attitude toward scripturalist religious origins is made to converge with the modern political ideologies that power modern political movements, Muslim fundamentalism subtends conceptions of history, society, state, and of political action that quite naturally freely draw on the universal modules of populism, vitalism, and the entire repertoire of standard anti-Enlightenment motifs in the history of European and non-European peoples.

Finally, insofar as Islamic fundamentalism, in its wide variety of national settings, ideological and sectarian inflections, and political orientations, was an ideology of increasingly wide appeal in the closing decades of the twentieth century, it shares the common socioeconomic characteristics of contemporary subalternist populist movements everywhere, both as diffuse sentiment and as centrally organized, party political movements of contestation and of revolution, mobilizing crowds as well as building up organizational structures and, in some extreme cases in Egypt, Algeria, Afghanistan, and some Western countries, resocializing their members completely and constructing countersocieties.

Intellectual Origins

Muslim Reformism

The ultimate intellectual, as distinct from social, origins of Islamic fundamentalism go back to the latter part of the nineteenth century. Much like right-wing European nationalist and royalist ideologies on the ascendant at the time, and in line with the long tradition of sentiment and polemic against the Enlightenment and the French Revolution associated with, among others, Johann Gottfried von Herder 1744–1803, Edmund Burke 1729–97, and Joseph de Maistre 1753–1821, these were premised upon a vitalist conception of society and history. At the heart of this conception lay the contention that societies and histories constituted natural organic wholes sundered and rendered into a condition of morbid distemper by the historical processes of modernity in its violent

revolutionary changes…. While these processes in Europe were identified as French Republicanism, socialism, and anticlericalism, in Muslim domains, and particularly in Ottoman lands, which were at the forefront of rapid change among Muslim peoples, they were identified with the state-led reforms in the domains of law, educational and cultural advancement, and modernist social engineering – all of which were galvanized by a positivist notion of historical evolution correlative with the assumption by the Ottoman state of direct control on the Bonapartist pattern, which saw cultural and legal hegemony as a primary task and prerogative.

Just as Herder and other conservative Germans derided the court of Frederick the Great as effeminate and 'inauthentic,' so the subaltern rungs of the emergent Ottoman bureaucracy and modern, nonclerical intelligentsia saw the reformist Ottoman state and the upper rungs of the state administration as being captive to European domination. These groups likewise saw this domination personified in westernized lifestyles and progressive ideas. Expressed initially by the Young Ottomans, these sentiments were vigorously expressed and most consequentially by the Persian Jamal al-Din al-Asadabadi, alias al-Afghani (1839–97) and his then disciple, the Egyptian Muhammad 'Abduh (1849–1905), through the medium of the short-lived, but highly suggestive, and influential review, *al-'Urwa al-Wuthqa*, *The Indissoluble Bond* (a Koranic expression), published in Paris in 1882–83.

It was suggested in this review that nations are corporate entities which cohere around moral drives, a notion which bears close comparison with Herder's notion of *Kräfte*. Once adulterated by foreign influences, these drives tend to atrophy, and to weaken the body-national which, in this social Darwinist world of nations, is perforce made subject to stronger parties. Thus history is a cyclical process, an alternance of purity and adulteration, corresponding to phases of power and powerlessness: in the history of Islam, *al-'Urwa al-Wuthqa* traced the causes of adulteration of the early Muslim empire to non-Arab newcomers to the faith, and to heterodox sects, and the adulteration of the Ottoman polity to the infiltration of modernist ideas and institutions of European provenance. Afghani and 'Abduh discounted race and ethnicity from their definition of a nation, and viewed religion as 'the sure bond' of Muslim nations. It was the Muslim religion, very broadly defined in culturalist and utilitarian rather than in devotional or dogmatic terms, which caused the organic unity of the nation to cohere, to acquire direction, and to gather force. Political action was thus conceived as an educational enterprise for the broad mass of people captive to superstition, and a conspiratorial political task directed at winning over prominent statesmen who might provide the authoritarian armature of this historical project.

Over subsequent decades, and until the late 1920s, the two prongs of this enterprise bifurcated, with Afghani, a charismatic and highly complex arch-conspirator but a superficial thinker, failing to build a Muslim internationalist coalition. 'Abduh, who became Grand Mufti of Egypt, independently charted the intellectual and cultural highlights of a lasting religious reform, explicitly inspired by the example of Luther, whose main thrust was to combat what he regarded as superstitious and irrational accretions that overcame what he took for the original Koranic foundations of the Muslim religion: folk religiosity, traditionalism, clericalism, and virtually all interpretations of religion that were contrary to modern science (including Darwinism) and modernist forms of political, legal, and social organization. At 'Abduh's hands, Islam became highly latitudinarian and episodically regarded almost as a natural religion corresponding to the social evolution of humanity. Reason and individual judgment *(ijtihad*) were highlighted as the true characteristics of Islam. Hence the modernist and reformist labels attached to this movement.

From Reformism to Fundamentalism

It was with 'Abduh's star pupil, the Syrian Muhammad Rashid Rida (d. 1935), initially as liberal as his teacher, that what might be termed political Afghanism became ascendant. In his monthly review *al-Manar* (1898–1934), published from Cairo and prodigiously influential all the way from Morocco to Java, he laid the foundations of an alliance between social conservatism and a cultural–political activism in the name of a religious reform shorn of its previous latitudinarianism, retained as a slogan voided of practical consequence, and with a pronounced antimodernist polemical tone that sought to expand the definition of religion to encompass the entire surface of social life, rendering politics, in the words of a prominent follower, 'social devotions.' The emphasis on the strict observance of ritual, the emblematic use of politicocultural spectacle such as extreme forms of punishment, the vituperative strictures against equally emblematic manifestations of modernity, particularly secularism and the social liberation of women, vigorous opposition to nearly all but literalist interpretations of the Koran and to miraculous and salvational views of Islamic history, and the hostility to modern legal reforms in the name of fidelity to Koranic and classical norms, propounding the 'restoration' of the *Shari'a* as a fundamental political slogan, and the revival of the notion of apostasy. These became leitmotifs of all subsequent Islamic fundamentalisms in the Arab World and beyond.

This expansive definition of religion was influenced by the example of the literalist revivalism of the Wahhabi movement which led to the foundation of the Kingdom of Saudi Arabia in 1932. This movement, born in a deprived and isolated territory during the era of the French Revolution, represented a ritualistic Puritanism which referred directly to the Muslim scriptures and certain fundamentalist figures in Muslim traditions, at the same time impoverishing these considerably, and reducing them to formulism. It is in this context that one begins to see that revivalism preceded reformism as a political movement in the Muslim world. It denotes Islamic movements that emerged in the eighteenth and nineteenth centuries. It was mainly confined to peripheral areas lying beyond the reach of central authorities. Its social base had a predominantly tribal formation. It articulated its outlook in the form of an internal Islamic dialogue. In the 1740s Central Arabia witnessed the formation of such a movement under the religious guidance of Muhammad b. 'Abd al-Wahhab and the political leadership of Muhammad b. Al-Sa'ud.

The Mahdist uprising in the Northern Sudan in 1881–85 was one of the last revivalist movements. This state survived

until 1898 following Lord Kitchener's reconquest. On the other hand, Islamic Reformism was an urban movement that came into being in the nineteenth century, and lasted well into the twentieth. Its leaders were state officials, intellectuals, or 'ulama' (religious leaders) fiercely opposed to traditional interpretations of religion. It conducted an open dialogue with European culture in an attempt to stem the tide of decline. By the middle of the twentieth century, both revivalism and reformism were superseded by the emergence of sovereign nation-states throughout the Muslim world.

These states carried out varied programmes of development and relegated Islam to a personal sphere (Turkey), or co-opted Islamic reformist ideas into state structures. Islam was for the first time dissected and revaluated under the watchful eyes of advancing expansionist Western European norms and concepts were inevitably borrowed or recast in this comparative endeavour. This was succinctly expressed by the Ottoman reform movement known as the Tanzimat 1839–1876 or 1800–1905, for the whole period of reforms. Reformists embarked on a search of viable cultural models. European progress was deemed as the direct outcome of intellectual developments leading to political liberty and economic progress. Martin Luther (1483–1546) was often considered a latter-day Muslim anxious to combat superstitions and restore religion to its original progressive nature.

It was in this historical juncture that the fundamentalism of Rashid Rida was widened to include an entire programme of political and social rejuvenation.

Culture into Politics

To this expansive definition of the religious sphere was added an organized political moment in the 1920s and 1930s with the emergence of the Society of Muslim Brothers, first in Egypt, later spawning similar movements elsewhere.

Incipient Organization

Like subsequent moments in the history of Islamic fundamentalism, this political emergence followed the rhythms and patterns of international history which, in the interwar period, was characterized by the anti-Enlightenment and antirationalist vitalist motifs that provided ideological sustenance to racism, hypernationalism, xenophobia, and cognate trends, both organized and socially diffuse. Thus, the Society of Muslim Brothers and its Muslim and Hindu homologs in India, the Jamaat-i Islami and the Rashtriya Swayamsevak Sangh, for instance, conceived themselves as sporting and paramilitary youth organizations, ostensibly beyond party and class politics in the name of the unity and homogeneity of the nation, conceiving of the state as a natural and organic emergence from a homogenous society, fully corresponding to its essence, momentarily in diremption and in the course of restoration to an Arcadian past prior to its violation and corruption by inauthentic modernity.

This rhetoric of history underlying a political project of hegemonism and of the seizure of state power by means both gradual (emphasizing reeducation and resocialization) and insurrectional, was given added ideological and systematic force and relevance in the period of the Cold War, with large-scale borrowing from state-led nationalism in Muslim countries and from populist conceptions of popular will, interpreted as fundamentally and abidingly religious, whereby Muslim peoples were thought to be, by natural instinct, Islamist in political orientation. This explains to a large degree the extraordinary degree of social, symbolic, and physical violence needed for nurturing these movements in their quest for power. Correlatively, these movements derived concrete logistical, institutional, and organizational sustenance from the United States and from Saudi Arabia, and may be said to have constituted the cultural plank of the Truman Doctrine, to which military and political aid was added, most dramatically in the Malay Peninsula in the 1950s, in Indonesia in 1965, and in Afghanistan in the 1980s.

Radical Islamism and Society

The main ideological innovation in this third phase of Islamic fundamentalism resides in the notion of *takfir*, the notion that Muslim societies are not only aberrant and unfaithful to their natural history, but that they are territories of degeneration and godlessness in need of a total recasting along models derived from the prophetic period in Islamic history, now transformed into a golden age. First propounded by Abul-A'la Mawdudi (1903–79), the founder of the Jamaat-i Islami in India and later its leading light in Pakistan, it was taken over by the Egyptian Sayyid Qutb (1903–66), crossed with the notion of degeneration current in right-wing European political thought during the *fin-de-siècle* and the interwar periods (prominent here was the influence of Alexis Carrel), and provided the cornerstone of the extremist fundamentalism of the 1990s: among certain groups in Egypt, Algeria, and Afghanistan, and more episodically elsewhere. Most specifically, the civil war in Afghanistan spawned a class of itinerant professional Islamist revolutionaries of various nationalities who took up arms in Algeria, Egypt, the United States, Bosnia, Kashmir, and elsewhere.

At the close of the twentieth century, further elements were added to the ideological and activist repertoire of these movements, some of which had taken over state power (as in Iran, Afghanistan, and Sudan) or became potent players on the national scene (as in Pakistan), where they have been directing operations of social engineering aimed at recasting laws and public mores. The most important of these elements, again reflecting international flavors of the time, is the hypernationalist use of the vitalist notions of 'identity,' of cultural difference, and their cognates in a situation marked by the waning of projects of development and their cultural and social correlates, the weakening of states in the developing world under conditions of global deregulation, including cultural and social deregulation. These derive sustenance from armies of the slum-dwellers, the structurally unemployed, small businessmen belonging to a previous age, and subaltern intellectuals including members of the clerisy, most potently, and successfully in Iran, where the breakup of the modernist state was most spectacularly displayed in the revolution of 1979 which has highly specific ideological and organizational characteristics.

An expansion of religious thought, in the name of culturally specific protocols of knowledge, led to an auxiliary and the most important element that sustains fundamentalist bids for intellectual hegemony, namely the institutional and

conceptual development of the 'Islamization of knowledge': Islamic social science, Islamic economics, Islamic democracy, the renewed hostility to Darwinism, and Islamic feminism. These currents of thought exercised collateral influence on sectors of political thought in many Muslim countries, some of them irreligious and hostile to political Islamism, and certain of these vocabularies seeped into the mainstream of political discourse, quite apart from state-sponsored religion which had hitherto been marked by a latitudinarian reformism, now feeling the need to protect its flanks and pushed into a more conservative direction.

Radical Islamism was thus a reactive movement that aspired to reinvent Islam according to its interpretation of the trajectory of world history, pronounced to be utterly secular, and consequently atheistic in its ultimate configurations. Hence, all societies, including Muslim countries, were deemed to have entered a new age of ignorance (*Jahiliyya*). This tragic calamity called therefore for radical solutions that had to cast aside the idea of reform. These solutions embraced the notion of Jihad as the most potent instrument prescribed for all believers in their endeavor to reinstate the true religion of God. Jihad became henceforth the sixth pillar of Islam (the five original pillars were belief in the oneness of God and the prophethood of Muhammad, Zakat or lams-giving, praying, fasting, and undertaking the pilgrimage to Mecca). Furthermore, Jihad was to be launched by a well-organized revolutionary vanguard steeped in the original tenets of Islam. This ideology received its most coherent elaboration at the hands of its Egyptian ideologue, Sayyid Qutb. His program of action was taken up by various Islamic groups with the gradual consolidation of Muslim nation-states and their modernist policies.

It was now thought that all previous attempts at building an Islamic state in the modern era had failed as a result of a number of interrelated factors: lack of a coherent ideology and a corresponding plan of action, coupled with the mistaken belief in the possibility of reforming existing institutions in a gradual and piecemeal manner. Such attempts at reform had failed, it was argued, because Islam could not be considered as a partial or disjointed collection of rituals and social practices. Islam is to be restored as a complete system of thought and practices, a weltanschauung, not unlike, fascism, Marxism, or liberalism. Each of these ideologies possesses its own repertoire of concepts, plans of action, constituencies, and political organization. Islam should in this sense differentiate itself clearly and emphatically in all its labels, slogans, tactics, and strategies. All societies had reverted to a new type of ignorance, irrespective of their political or cultural designations. Consequently, two mutually opposed camps should face each other across well-demarcated fields: those who uphold belief in the only authentic message of God, and all others, irrespective of their varied designations – democratic, communist, socialist, nationalist etc. – particularly those who deceitfully pretend, in spite of all evidence to the contrary, to be applying the precepts of Islam. In other words, Jihad launched by a revolutionary vanguard becomes a religious obligation that is incumbent on all those who look forward to the foundation of an Islamic state. It is, moreover, a worldwide movement that recognizes no borders, national territories, or international conventions. However, it was initially supposed that this religious duty, whose highest form was armed struggle, or indiscriminate violence, was to be carried out against the immediate enemy, or the national state. This was the case in the 1970s, 1980s and early 1990s, with Egypt, Syria, and Algeria figuring as the most conspicuous cases. As hopes of a speedy victory began to fade owing to repressive measures and counterterrorist policies pursued by expanded intelligence and security services of these national states, a new approach began to be formulated. This was especially the case of al-Qa'ida organization that was originally set up in the 1980s to combat the Soviet military presence in the country in close cooperation with the United States, Saudi Arabia, and Pakistan. With the Soviet withdrawal from Afghanistan in 1989 and the subsequent downfall of its communist-led government in 1992, al-Qa'ida, under the leadership Osama Bin Laden, a Saudi millionaire, tried to diversify its activities by launching suicide and other operations in Muslim countries, with no long-lasting results. Shunned by Saudi Arabia and the United States in the wake of their victory in Afghanistan, and faced with efficient repressive regimes across the Muslim world, Osama Bin Laden and his Arab recruits and disciples, along with other Jihadist groups, took the crucial decision of transforming their struggle into an internationalist encounter pitting the West and other secular states against an Islamist organization that perceived Jihad as a relentless series of violent acts designed to sow terror, intimidate the enemy, and lead to the final collapse of an unjust and ungodly world system. It was in this context that the attack on the twin towers of the World Trade Center and the Pentagon took place on 9 September 2001. Between 2001 and 2010 the West coined its own term, war on terror, to describe or justify its military, political, and surveillance operations across the world. Beginning with the invasion of Afghanistan in 2001, and Iraq in 2003, and ending with illegal practices ranging from the irregular rendition of suspected persons, or the extrajudicial transfer of a suspect from a Western state to non-Western one whereby torture could be inflicted with impunity, and setting up in the United States a surveillance system of phone tapping, email, and private correspondence interception. In this sense, Jihadist indiscriminate violent operations were often overshadowed by indiscriminate response and illegal violations of human rights, not to mention the national sovereignty of independent states.

The eruption of the Arab Spring at the end of 2010 marked a new watershed in the fortunes and future prospects of Islamic fundamentalism. This was most clearly pronounced in the bifurcation of the movement into two branches, with one espousing the pursuit of a peaceful pathway to political power, and the other accentuating its rhetoric of continuing its armed struggle until the final Day of Judgment. Moreover, the internationalist phase seems to have been unceremoniously discarded without official burial notices. This act received its recent confirmation in the eruption of a peaceful uprising in Syria, in line with other Arab Spring countries, only to be transformed within 2 years into a violent civil war, with Jihadists pouring into Syria from all over the World. Such a state of affairs indicates the emergence of a new Islamic fundamentalist paradigm which combines national and extra-territorial elements in an effort to stem the tide of secular change deemed harmful to the intrinsic nature of a specific and narrow version of Islam. It is, however, doubtful whether such a strategy will yield permanent results in the face of increasing

numbers of Muslim individuals, organizations and states embracing and applying democracy as a preferred system of government and means of resolving social and political differences and diversities. This is the case in Indonesia, Turkey, and Tunisia, to mention only a few. The example of the Muslim Brothers in Egypt is another case in point, whereby they lost power within a year of winning parliamentary and presidential elections in 2013. This indicates that citizens become almost immediately disillusioned with a movement that uses a religiously saturated call to action without a corresponding ability to deliver some of its widely trumpeted promises, albeit in an ambiguous language that most strategists find difficult to translate into concrete achievements. Lacking a clear social and economic program, these movements seem to excel under certain conditions in gaining the support of some sections of their populations, but once in power this support rapidly evaporates, leading to their ignominious downfall, as was the case in Egypt. Furthermore, Western governments are revising their traditional policies, adopting in the process more nuanced stances that may in the long-term eventuate in more balanced strategies and political decisions ranging from the feasibility of military confrontations to targeted economic aid.

Given these new political and social developments, Islamic fundamentalism no longer seems as the wave of the future. Nevertheless, such a diagnosis does not preclude the persistence of certain movements and individuals to swim against the tide or commit suicide in the name of a distorted version of their own religion.

Abstract

'Islamic law' refers to the diverse legal systems that have been and continue to be produced with the objective of being in line with the Islamic faith. This article provides an overview of Islamic legal history and a basic explanation of orthodox Islamic jurisprudential methodology that demonstrates the diversity, flexibility, and breadth of Islamic legal systems.

Introduction

'Islamic law' refers to the diverse legal systems that have been and continue to be produced with the objective of being in accord with the Islamic faith. Islamic legal systems operate in multiple and sometimes discontinuous ways. Usage of the singular term 'Islamic law' should not be understood as suggesting the absence of legal polycentricity (multiple groups and institutions generate Islamic law) or legal pluralism (within Islamic societies, since Islamic and non-Islamic legal systems coexist). There are significant historical and substantive distinctions between 'Islamic law' and 'Muslim legalities' (the legal systems in use by Muslims). 'Islamic law' refers to juristic interpretations (*fiqh*) of divine law (*sharīʿah*); 'Muslim legalities' refers to either state law (where Muslims are the majority or minority) or the legal practices of non-state Muslim communities. The key distinction between these two overlapping categories is that Islamic jurisprudence is generated by an interpretive process anchored in canonical Islamic texts; in comparison, Muslim legalities are generated by an interpretive process anchored in a state or other legal system that may or may not be Islamic and with a population that may or may not have a Muslim majority (Salaymeh, 2014). The historical section on Islamic law in this article focuses on Arabia and other parts of the Near East, but Islamic law spread internationally by the beginning of the modern era. This article provides a basic overview of Islamic legal history and key aspects of Islamic jurisprudence.

Common Terms and Concepts	
Qurʾān	Islam's holy book, revealed to Muḥammad (d. 632)
sunnah	Normative precedents of the earliest Muslim community
ḥadīth	Reports of the sayings and acts of Muḥammad and some of his early companions; compiled in canonical collections
sharīʿah	Divine law
fiqh	Human understanding or interpretation of divine law
faqīh	Jurist, one who interprets divine law
uṣūl al-fiqh	Principles for interpreting divine law

(*Continued*)

—cont'd

Common Terms and Concepts	
ijmāʿ	Legal consensus of Companions or of Muslim community
qiyās	Analogical reasoning
ijtihād	Independent legal judgment
taqlīd	Following established legal precedents
fatwá (pl. fatāwá)	A nonbinding legal opinion issued by a jurisconsult (a specific kind of jurist qualified to give legal advice), sometimes in response to a question
muftī	A jurisconsult, meaning a jurist qualified to formulate Islamic legal opinions
qāḍī	Judge
madhhab (pl. madhāhib)	Around the eighth century, referred to a group of students, jurists, and judges who adopted the doctrine of a particular leading jurist; later referred to the following of a particular legal school

Islamic Legal History

The periodization presented here identifies approximate moments in Islamic legal history and is not intended to convey developmental or evolutionary progress.

Legal Circles and Networks (*c.* CE 610–750): The Beginnings of Islamic Law

Islamic legal history begins with Prophet Muḥammad's judgments over the first Muslim community in both Mecca (*c.*610–622) and Medina (*c.*622–632). Some of these laws were recorded in the Qurʾān and others were orally transmitted as ḥadīth. To derive legal rulings, the Prophet's Companions and the first generation of Muslims after them (known as the Successors) interpreted the Qurʾān and sunnah and expressed personal opinions (*rāʾy*) or interpretations of Islamic law; in generating Islamic law, they both innovated new laws and followed legal precedents (of the Prophet, Arabian customs, and broader Near Eastern legal practices). As was the case for the general transmission of knowledge in the region, legal education occurred primarily in study circles

around particular scholars (Companions or Successors), who sometimes served as judges in local courts. Jurists with a reputation for piety or learning attracted larger circles of students.

With the Muslim conquests and the establishment of the Umayyad Empire (CE 661–750), Muslims created a burgeoning empire and integrated the region's diverse religious and ethnic communities – as well as some of their legal practices. While legal education initially took place in legal circles (local schools), they evolved into legal networks (geographic or personal schools, following a reputed jurist), and later consolidated into legal schools (*madhāhib*, groups of legal professionals following a particular jurisprudential methodology). Legal circles were informal groups of students who sat around a teacher (in a circle) to memorize and discuss wide-ranging Islamic legal and historical traditions; these local legal circles often met in mosques or private homes. Legal networks were larger, more formal groups of students who studied with a teacher to memorize and discuss a limited set of legal and historical traditions; meeting in mosques, homes, and informal academies, these networks comprised both students who were local to the teacher's community and those who traveled from afar in order to study with the teacher. Many of these teachers were also jurists who served the legal needs of their communities. Traditional Islamic sources identify seven jurists in Medina as having been influential: Abū Bakr ibn ʿAbd al-Raḥmān al-Makhzūmī (d. 712/3), Khārija ibn Zayd ibn Thābit (d. 717–9), ʿUrwa ibn al-Zubayr (d. *c.*715), Sulaymān ibn Yasār al-Ḥilālī (d. 718/9), ʿUbayd Allāh (d. 716/7), Saʿīd ibn al-Musayyab (d. 712/3), and al-Qāsim ibn Muḥammad (d. 728). Jurists outside of Medina also gained fame; for example, famous jurists in Mecca included ʿAṭāʾ ibn Abī Rabāḥ (d. 723) and Mujāhid ibn Jabr (d. *c.*720) and in Kufa included Ibrāhīm al-Nakhaʿī (d. 714) and Ḥammād ibn Abī Sulaymān (d. 737) (Hallaq, 2005: p. 65).

There was a spectrum of Muslim juristic approaches, with one end comprising rationalists (*ahl al-rāʾy*, primarily in Iraq) and the other end consisting of traditionists (*ahl al-ḥadīth*, primarily in Ḥijāz). Rationalists anchored jurisprudence in logical thinking, whereas traditionists anchored jurisprudence in sacred and textual sources (Hallaq, 2009: pp. 55–60). Muslim jurists of this period cannot easily be categorized as belonging to one camp or the other because most jurists likely combined approaches, by both relying on textual authorities and engaging in logical reasoning in formulating legal opinions. Shīʿī sectarianism led to the development of another approach, based on the legal authority of Caliph/Imām ʿAlī and his Imāmī successors. The largest Shīʿī legal school is the Imāmī one – sometimes identified as the Jaʿfarī school, after the fifth and sixth Imāms who lived in the late seventh through mid-eighth centuries; it was initially strongest in Medina and Kufa.

Professionalization of Legal Schools (*c.* CE 750–950)

After the ʿAbbāsids (r. 750–1258) established Baghdad as the political-intellectual capital (in CE 762) of the Islamic empire, jurists shifted from associating with legal circles or networks to identifying with professional legal schools (*madhāhib*). Parallel to the ʿAbbāsid Empire's development of an increasingly more complex bureaucratic system, Muslim jurists became professionalized – as evidenced in their literature, education, and organizational structures. Islamic legal literature initially integrated historical narratives and recorded legal judgments, but Muslim scholars gradually differentiated genres (historiography, Qurʾānic interpretation, ḥadīth studies, and law) as the juristic profession became more specialized. Muslim jurists debated the role of oral law – the orally transmitted traditions about the legal practices of the earliest generations of Muslims – in Islamic jurisprudence; challenges to the authority of oral reports led to the increasing importance of recorded (written) ḥadīth. Consequently, a broad synthesis of the rationalist and traditionist approaches to jurisprudence took place in this period.

Similarly, Islamic legal education became more professionalized. Islamic law was initially taught in mosques and in private homes; but the demands of students and scholars traveling in search of religious knowledge led to the establishment of hostels and the organization of more dedicated spaces of learning. The college of legal studies (*madrasah*) gradually emerged in Iran and Iraq to provide spaces for instruction and libraries, in addition to housing for professors and students. But these buildings served additional communal functions, as they often included tombs or public fountains. Law students studied with many scholars in many places, not being limited to one legal school; in turn, their travels resulted in the diffusion of legal methodologies to new areas.

Over the course of the first four centuries of Islam, hundreds of legal circles and networks emerged and disappeared. The legal reasoning and doctrines of these now extinct legal circles and networks are difficult to reconstruct from the available historical sources. They were incrementally superseded by legal schools, for which we have more historical evidence – particularly those that survive; this situation of the historical evidence can result in overemphasizing the results of a long historical process, rather than the sociopolitical dynamics that produced the consolidation of legal schools. Among the extinct legal schools, most scholarly attention has been focused on the schools of three jurists: al-Awzāʿī (d. 773; Syria), al-Ẓāhirī (d. 883; Iraq), and al-Ṭabarī (d. 922; Iraq).

The ʿAbbāsid state's demand for professional jurists and sectarian resistance encouraged the consolidation of Islamic legal schools from hundreds to several. The eponyms of the surviving legal schools flourished in this era: Abū Ḥanīfah (d. 767; Kufa, Iraq), Mālik ibn Ānas (d. 795; Medina), al-Shāfiʿī (d. 820; Egypt), Aḥmad ibn Ḥanbal (d. 855; Baghdad, Iraq). Each school is known for a particular characteristic: Ḥanafīs for their reliance on personal opinion, analogical reasoning (*qiyās*), and juristic preference (*istiḥsān*); Mālikīs for their prioritization of Medinan practice (*ʿamal*) and consensus (*ijmāʿ*); Shāfiʿīs for their synthesis of rationalist and traditionist methodologies; Ḥanbalīs for their avoidance of reasoning in favor of textual sources. Still, it would be a mistake to reduce the complexity of these legal schools to these common motifs or assume that these jurists and their students represent all Islamic legal activity of this period. It was not until the beginning of the tenth century, at the earliest, that these legal schools became clearly identified, especially in terms of a particular jurisprudential methodology (Hallaq, 2009: pp. 60–71). In addition, legal schools sometimes played sociopolitical roles.

For instance, throughout the ninth and tenth centuries, Ḥanbalī preachers occasionally raised popular demonstrations for or against Caliphal policy, but the school is known for generally avoiding political controversies (Lapidus and Salaymeh, 2012b).

Coinciding with the rise of formal institutions of learning and the consolidation of the schools of law, there was an increase in the importance of the jurisconsult (*muftī*) – a jurist qualified to formulate Islamic legal opinions. A legal decree consisted of both the question sent in writing to the jurisconsult and his answer. In addition, judges often consulted with jurisconsults for their expertise in complicated cases, as evidenced by the inclusion of a jurisconsult's legal decree within the court register. The earliest surviving collections of a jurisconsult's opinions (plural, *fatāwá*) date to the tenth century. The general public consulted a jurisconsult in ways similar to how we now consult attorneys for legal advice; some individuals 'shopped' for a legal decree (singular, *fatwá*), asking several jurisconsults until they obtained a desired outcome.

A judge (*qāḍī*) was responsible for the administration of the courts and selected both his own court recorders and witness certifiers (responsible for evaluating the reliability of witnesses). Judges were also involved in managing charitable endowments and, sometimes, managing the assets of orphans. While court recorders wrote down case proceedings, these documents were not effectively preserved and Islamic court records are largely lost for periods before the sixteenth century. The ʿAbbāsids appointed the first chief judge (*qāḍī al-quḍāh*) – Abū Yūsuf (d. 798), a Ḥanafī scholar – in the late eighth century.

In addition to the formal court system, there were other judicial or quasi-judicial institutions. As early as the ʿAbbāsid Caliph al-Mahdī (r. 775–785), if not earlier, Muslim rulers heard complaints or petitions in courts of equity (*maẓālim*). As under pre-Islamic rule, market-inspectors acted on behalf of the state to ensure fair dealings in the marketplace, which evolved into enforcing morally proper behavior. Reflecting the professionalization of legal knowledge, jurists produced a genre of legal literature (*ḥisbah*) that delineated the duties and limitations of a market inspector.

Consolidation and Formalization (*c.* CE 950–1250)

Professionalization of jurists and institutionalization of learning contributed to the growing dominance of a religious orthodoxy. Diversity of opinions on a variety of legal and theological matters gradually became narrower and, after the tenth century, a religious canon becomes discernible. By the eleventh century, the majority of Muslim jurists appear to have identified with one of the still extant Sunnī legal schools (Ḥanafī, Shāfiʿī, Ḥanbalī, or Mālikī). (Other extant schools include Imāmī Shīʿīs and Ismāʿīlīs, as well as Ẓāhirīs (literalists), Zaydīs, and Khārijīs.) Legal schools succeeded or failed based on popular support, the sociopolitical influence of the school's jurists, and the compatibility between local, customary practices, and the school's legal opinions. A legal orthodoxy emerged through the consolidation of the main legal schools and the gradual marginalization of peripheral or minority legal schools. The four surviving Sunnī legal schools grew in terms of number, power, and influence for a variety of both internal (i.e., legal education and popular appeal) and external (i.e., state support) reasons. In eleventh and twelfth century Nishapur, Ḥanafīs and Shāfiʿīs struggled for local political power over the judiciary, academies, and charitable endowments; these struggles affected the influence of each legal school in the region. Yet, an individual Muslim's identification with a 'legal school' did not necessarily indicate a commitment to the legal school's jurisprudence; common people were loyal to local leaders and not necessarily to the abstract principles of the legal school.

Within this consolidation process, identification with a particular legal school was not necessarily exclusive. Law students studied with scholars outside their own legal school – particularly ḥadīth transmission – and freely switched legal school affiliation. Since caliphs appointed a chief judge who, in turn, oversaw the appointment of judges throughout the empire, jurists increasingly tended to associate with the larger, state-backed legal schools. Some jurists shifted their legal school affiliation in order to procure administrative or judicial appointments. Indeed, as legal education became more systematized and salaries of judges increased, the legal profession most likely attracted students drawn to the pragmatic – rather than spiritual or intellectual – aspects of the vocation of law. In terms of producing the most influential jurisprudential texts, the most important jurists were unaffiliated with the state.

The formalization and professionalization of the legal schools are reflected in changing genres of legal literature. In later periods, the legal opinions of groups of jurists who belonged to the same legal school were compiled, as opposed to the opinion of a single jurist. Muslim jurists wrote commentaries on canonized or codified legal texts of groups of predecessor jurists (who had been identified as authoritative) and created condensed legal manuals (plural, *mukhtaṣarāt*). *Mukhtaṣar* (singular) texts abbreviated earlier legal texts to offer straightforward legal answers based on each school's most authoritative or widely accepted legal opinions; these abridgements became the main texts of study for students and became increasingly prevalent after the eleventh century. By selectively choosing which legal opinions would be considered authoritative, these compendia created an official resource for later jurists to perpetuate and disseminate the rulings and the methodology of their school. Another genre of legal literature that intensified in this period is texts on the etiquette of judging (*adab al-qāḍī*). Based on earlier court practices, these texts outlined the duties and proper behavior of a judge and general court procedures, thereby further formalizing the legal profession.

Beginning in the tenth century, legal education became increasingly formalized as professional law colleges (*madāris*; singular, *madrasah*) were endowed with permanent sources of income, such as land or rent-bearing urban property, set aside in perpetuity. These endowed trusts (*awqāf*) funded faculty salaries, student stipends, religious clerical staff, administrative staff, and maintenance staff (janitors, gate keepers, etc.). Donors created these endowed trusts in order to prevent their property from being divided in accordance with inheritance laws or from being confiscated by the government. These trusts also allowed donors to identify individuals (especially daughters) who could receive a regular income from the endowment. Endowing colleges gave the donor prestige.

Niẓām al-Mulk (d. 1092), a Seljuq minister, made it the state's policy to support Islamic educational institutions and endowed both Ḥanafī and Shāfiʿī colleges in all of the empire's major cities. While the colleges were initially dedicated to only one legal school, the Mustanṣiriyya college (founded in Baghdad in 1233) was devoted to several legal schools (Lapidus and Salaymeh, 2012b).

Jurist-professors designed the curriculum of these colleges, which varied according to local practice and the legal school affiliation. In previous centuries, jurists typically had earned their living through trade or craftwork, but with the institutionalization of education in the form of endowed colleges, religious scholars became professionals, administrators, and salaried employees. Through state patronage, salaries, and the administration of endowments, scholars became a professional class. Islamic legal education was basically informal, flexible, and built on individual teacher and student relationships, rather than institutional ties; students did not earn grades or receive degrees. Learning revolved around the reputation of a respected scholar, who in his individual capacity could give students a specific license to teach, to transmit ḥadīth, to judge, or to participate in scholarly debates – depending on the course of study. In addition to law, many colleges taught Qurʾān, ḥadīth, Arabic grammar, theology, Sufism, medicine, and philosophy. These colleges consolidated informal legal instruction into an official institution with a physical center and permanently endowed funds, thereby facilitating professional full-time study of Islamic law and the expanded training of cadres of Islamic legal teachers and administrators (Lapidus and Salaymeh, 2012b).

Still, a typical student 'heard' (i.e., listened to and memorized oral lectures) his subjects from a variety of teachers on a variety of topics in a variety of places and study circles. Education occurred beyond colleges and the function of colleges extended beyond education (into religious propaganda and political action). In addition to endowed colleges, the transmission of religious knowledge took place in informal study circles (*ḥalaqāt*; s. *ḥalaqah*), in public mosques, and in private homes; students could come to a college without being a resident or receiving a stipend. Women not only studied with relatives, but also received certificates from outside scholars, including women scholars; they most commonly transmitted ḥadīth. College professors, Qurʾān and ḥadīth reciters, and storytellers all had audiences with the general public. Both formal colleges and informal learning circles encouraged the consolidation of the surviving legal schools by training students to further propagate the law school's methodology (Lapidus and Salaymeh, 2012b).

Technocratization (*c.* CE 1250–1450)

By the thirteenth century, Muslim jurists were increasingly becoming technocrats, specialized in knowing the doctrinal rulings of a particular school – rather than in applying the Islamic jurisprudential methodology of a particular school. In this era, Muslim jurists composed more abridged versions of canonical legal commentaries and the locus of jurisprudential activity was shifting away from the Iraqi sphere of influence (both geographically and intellectually). This was likely a result of the Mongol destruction of Baghdad (capital of the ʿAbbāsid Caliphate) and its libraries in 1258. The city's role as an intellectual center came to an end as regional centers of intellectual production arose to replace it. In provincial centers of legal activity, legal manuals and their commentaries were produced; in particular, one type of abridged Islamic legal text – sometimes identified as a 'common law *mukhtaṣar*' (Fadel, 1996) – became prevalent.

The Mamluk Sultanate (r. 1250–1517) of Egypt appointed a chief judge for each of the four main Sunnī legal schools, solidifying the position of the largest schools and confirming the demise of the once numerous smaller schools. A potential consequence of these juristic appointments was that the Mamluk Sultan used these four legal options to his advantage, by selectively seeking legal decrees from the legal school most likely to meet his objectives. The daily operations of Mamluk courts are preserved in the fourteenth century court documents archived in Jerusalem's Islamic museum. While generally jurisconsults were not affiliated with or regulated by the state, the Mamluks did appoint some jurisconsults to courts of equity. In the eleventh century, jurists had defined a jurisconsult as being a *mujtahid* (i.e., one who has the ability to independently reason; the highest rank of a jurist). By the middle of the thirteenth century, however, it appears that the prerequisites were lowered and a jurisconsult was expected by most scholars to be a *muqallid* (i.e., able to articulate a legal opinion based on the precedents and methodology of a particular legal school; a lower rank than *mujtahid*). This reflects a far reaching phenomenon in this era: many Muslim jurists preferred to follow the legal opinions of their predecessors in orthodox legal schools (*taqlīd*), rather than develop legal opinions based on the jurisprudential methodology of an orthodox legal school (*ijtihād fī al-madhhab*).

Bureaucratization (*c.* CE 1450–1800)

The Ottoman Empire (r. 1299–1923) bureaucratized Islamic legal practices of preceding periods by making law an essential component of the state's administrative apparatus. After the fifteenth century, Ottoman courts became the primary venue for litigation throughout the Ottoman Empire. Ottoman courts applied Islamic legal precedents (specifically, *fiqh*) in a judicial system characterized by its systematization. Following the precedent of the Mamluks in Egypt, the Ottomans officially appointed a jurisconsult (*muftī*) to provide formal legal opinions, thereby integrating these formerly independent legal thinkers into the state bureaucracy. Although the training of legal professionals had previously been controlled primarily by jurists with minimal state intervention, the Ottoman state became intimately involved in every aspect of judicial activity – from training jurists and court personnel, to selecting judges and applying legal codes. The Ottomans established schools in the cities/towns they conquered and made the Ḥanafī legal school the state's official legal school. As a result, law students began to migrate away from other legal schools to seek training in the Ḥanafī school as a step toward a career in the government (Lapidus and Salaymeh, 2012a).

The Ottomans systematized law throughout the empire by promulgating legal codes, such as the *qānūnnāme* (code of regulations) of 1519 and the criminal code of 1540. Having been composed in both Ottoman Turkish and Arabic, the *qānūnnāme*'s language indicates that Arabs under Ottoman rule

were expected to conform to Ottoman laws, which were based on both medieval Islamic jurisprudence and customary laws (Ergene, 2001). The Ottoman criminal code changed a variety of criminal penalties into fixed fines (proportional to the offender's economic means) and permitted some circumstantial evidence in determining adultery, but otherwise largely continued earlier Islamic legal practices (Imber, 1996). Legal codes were enforced by Ottoman judges in official, newly established Ottoman courthouses, which were more numerous when compared to the pre-Ottoman period. Ottoman court fees for litigating cases and for official documents (deeds, marriage certificates, etc.) financed the court's operational costs and even contributed to the Ottoman treasury (Ergene, 2002).

Despite the proliferation of Ottoman courts and laws throughout the empire, there was some local resistance to Ottoman legal hegemony. Some Ottoman subjects objected to some Ottoman laws on the grounds that they were not based on 'Islamic' legal principles. By way of example, in the eighteenth century, a local, provincial judge objected to two types of taxes (*avarïz* and *nüzül*) because he believed they were impermissible according to *sharīʿah*. (Ergene, 2001: p. 83) This tension was part of an ongoing debate about the relationship between Ottoman laws and the legal precedents established by the medieval Islamic legal schools. Ottoman jurists invoked Islamic jurisprudential terminology – such as *ḍarūra* (necessity) and *maṣlaḥah* (public interest) – to legitimate setting aside certain precedents (recorded in the jurisprudential texts of the orthodox legal schools). Similarly, local customs could prevail over the legal opinions recorded in jurisprudential texts. Thus, the Ottoman acceptance of usury should be understood as an Ottoman interpretation of Islamic scripture that differed from the medieval orthodox position. What makes the Ottoman period distinctive in Islamic legal history is the state's participation in legal activity, not the legal outcomes of a normative jurisprudential process.

The pinnacle of the Ottoman state's control over legal matters was the Ottoman *şeyhü'lislām (shaykh al-Islām)*, who acted as a leader of Ottoman religious scholars and chief jurist of the Ottoman state. He issued legal decrees and intervened in political matters by issuing legal opinions related to the state's foreign policies. Molla Hüsrev (d. 1480) was a fifteenth century *şeyhü'lislām* who wrote about Islamic law in Arabic. Likewise, Ibrahim b. Muhammed al-Halebi (d. 1549) wrote in Arabic (since he was from Egypt) and his work was translated into Turkish in the seventeenth century. Ebu's-su'ud (d. 1574) was one of the most well-known Ottoman jurists to hold the position of *şeyhü'lislām*. Ebu's-su'ud gave the Ottoman sultan the title of Caliph, justified interest-loans, and modified tax practices (Imber, 1997). Collections of legal decrees – such as *Behçetü'l-fetāvā* by Yenişehirli 'Abdullāh, who was *şeyhü'lislām* from 1718 to 1730 – provide scholars with important information about daily life and legal practices of the Ottomans.

Law in any society is not merely the product of the state or legal elites, but also is informed by local groups and interests. Guild law, for instance, was independently developed and Ottoman courts honored their customs in adjudicating disputes between guild members. Similarly, Ottoman judges (like judges in any legal system) sometimes deferred to customary law, thereby legitimating local customs as a source of law. By the way of example, the Ottoman *qānūnnāme* introduced a local custom by fining a man who was aware of his wife's infidelity, but did not act upon that knowledge (Imber, 1996: p. 185). In response to local customs, some Ottoman legislation was promulgated to deal with customary realities that do not appear to have been dealt with by medieval Muslim jurists. Records of complaints against Ottoman officials – such as the *Şikayet Deferi* of 1675 – indicate that lower class Ottoman citizens had recourse to the courts against government elites. This suggests that the Ottoman courts were not merely tools used by the elite to dominate society (Lapidus and Salaymeh, 2012a).

Some powerful interest groups were able to acquire exceptions to Ottoman laws that resulted in economic advantages. In the seventeenth and eighteenth centuries, the Ottoman Empire granted legal rights (*ahdnames*) to foreign merchants who were enabled to conduct commercial dealings according to foreign, rather than Ottoman, laws. The agreements dictated everything from customs rates, to taxation, to inheritance laws that would apply to both foreign merchants and non-Muslim Ottomans associated with them (effectively changing the nationality of the latter). These Ottoman capitulations eventually became a pretext for European intervention into internal Ottoman affairs (Lapidus and Salaymeh, 2012a).

A common Western stereotype about the nature of the Ottoman state as despotic has been refuted by numerous studies demonstrating that power was decentered through the Ottoman bureaucracy and that there were legal limits to the Ottoman sultan's power. A combination of tradition and bureaucracy prevented a sultan from indiscriminately using his power. Sultan Süleyman (d. 1520) was known as the lawgiver and acquired a reputation for justice by punishing Ottoman administrators who had abused their power. Süleyman promulgated legislation (known as *kanun*) and compiled the judgments of predecessor Ottoman sultans in his legal code, the *kanun-i Osmani*, which was the law of the Ottoman Empire for several centuries. Other sultans passed regulations that introduced or limited a variety of legal practices. For example, after 1544, Ottoman judges were prohibited – by sultanic order – from conducting marriages without the permission of a woman's guardian (a legal option permitted by Ḥanafī *fiqh*) (Lapidus and Salaymeh, 2012a).

Another common stereotype about Ottoman judges is embodied in the term coined by Weber, *kadi justice*, which refers to a judge who has unlimited personal discretion. Ottoman court records, however, illustrate that Ottoman judges actually followed well-known procedural and substantive rules. Indeed, later Ottoman judges were bureaucrats and their method of adjudication was as systematized as other Ottoman administrative acts. While multiple, sometimes conflicting, legal entities operated in the fourteenth and fifteenth centuries, these were subsequently centralized by the Ottoman state (Lapidus and Salaymeh, 2012a).

Islamic law also existed outside the Ottoman Empire and other empires played similar roles in codifying Islamic law. Awrangzīb, Mughal Emperor of India, ordered the compilation of an Islamic law compendium based on the most authoritative legal opinions of the Ḥanafī school; the result is known as *al-Fatāwá al-ʿĀlamgīrīyah* (compiled between CE 1664 and

1672) and the text was an important reference work throughout South Asia and beyond for generations.

Colonialism and Reformation, Liberalization and Authoritarianism (*c.* CE 1800–2010)

Whether through direct occupation or indirect political and economic pressure, Western colonial interventions in the Muslim world provoked a variety of legal reforms and legal innovations. During and after colonization, many Muslim-majority states merged civil or common-law traditions from the West with Islamic legal traditions. Some of these changes were prompted by the needs of modern nation-states and modern administrative practices, while other changes were triggered by socioeconomic and political pressures. These processes generated the distinctions between 'Islamic law' and 'Muslim legalities.' The 'secularization' of law that began with Western colonialism led to the emergence of these overlapping spheres of legal activity. Muslim jurists continued to teach and implement Islamic legal traditions, while secular legal professionals practiced law in states that happened to have Muslim-majority populations. For more detailed information on how these modern distinctions between 'Islamic law' and 'law in Muslim majority states' (or 'Muslim legalities') play out in some parts of the Muslim world, please *see* Middle Eastern and North African Legal Traditions.

Western commercial and penal codes were gradually adopted throughout the Muslim world in the nineteenth and twentieth centuries. South Asia, for example, was incorporated into the British common law system. The Ottoman Empire pursued a legal reform movement (*Tanẓīmāt*) that led, in 1847, to mixed courts with European and Ottoman judges and, in 1850, to a commercial code in line with the global market economy. In addition, a series of 'land reform' laws were passed during the mid-nineteenth century – such as an Ottoman law (1858) and a series of French laws in Algeria (1856–73) – that resulted in the privatization of land. This, in turn, facilitated colonial purchases of land throughout the Middle East and North Africa; in some areas, colonialists owned between 20 and 25% of land. One of the more widely known works of Islamic legal reformation is the *Mecelle* (1869–76), which was issued by the Ottoman government as an attempt to codify Ḥanafī laws in the areas of transactions and some court procedures. Ottoman capitulations permitted Europeans to operate their own courts in the Ottoman Empire, thereby bypassing Ottoman legal sovereignty; this resulted in significant economic advantages for Europeans living in Ottoman territories.

Islamic constitutionalism appears to have begun in the late nineteenth century, with the drafting of constitutions in Tunisia (1861) and in the Ottoman Empire (1876), but intensified with the Iranian constitutional revolution (1906–11) (Arjomand 116–7). While Islamic law was initially understood as a limit on governance, it eventually became identified in various constitutions as a source of law. By 2000, approximately 24 Muslim-majority states identified Islamic law as a (or 'the') source of law (Arjomand 123). Some countries abolished Islamic courts, while other countries established and maintained two parallel court systems (one civil and the other Islamic).

Islamic reform (*iṣlāḥ*) movements, with a special focus on legal issues, emerged in response to colonialism and broad regional legal reforms. There were two common responses to this situation: first, a rejection of the orthodoxy of legal schools and a return to the primary textual sources of Islamic law (advocated by different streams of Salafīs); second, an attempt to combine the legal opinions of both the orthodox and extinct legal schools, relying on the objectives and legal necessity of Islamic legal theory (advocated by the Muslim Brotherhood). Muḥammad ibn ʿAbd al-Wahhāb (d. 1787) preached that Muslims should establish laws based on the Qurʾān and sunnah, instead of relying on the orthodox legal schools; his ideas remain influential today. Many Muslim intellectuals and activists who were involved in the socio-political changes of the nineteenth and twentieth centuries were legal thinkers who advocated certain positions vis-à-vis law. Rifāʿah al-Ṭaḥṭāwī (d. 1873) studied in France and returned to his home country of Egypt where he advocated for modifying Islamic legal traditions based on social need. Among the more influential Sunnīs were the Egyptian grand muftī Muḥammad ʿAbduh (d. 1905) and his student, the Syrian Muḥammad Rashīd Riḍā (d. 1935). Both scholars proposed Islam – and adherence to Islamic law in particular – as essential to colonial resistance. ʿAbduh (d. 1905) issued numerous legal decrees and advocated for choosing (*takhayyur*) the most suitable legal opinion from across the orthodox Sunnī legal schools or combining (*talfīq*) legal opinions from different schools. Riḍā (d. 1935) articulated Islamic reform as a return to the ways of the earliest generations of Muslims, the *salaf* (from which is derived the term *salafī*). Hassan al-Bannā (d. 1949) was the founder of the Muslim Brotherhood, a Muslim social and political party in Egypt. A number of academies and institutions were established or strengthened with the intention of 'revitalizing' Islamic law throughout the Muslim world during the twentieth century. Yet legal education was increasingly secularized and legal actors with training in Islamic law primarily engaged the private sphere or served the public in family law.

Recent debates about the authority of Islamic legal traditions are one aspect of an Islamic revival movement that began in the 1970s as a reaction against the legacy of European colonialism in the region. The reliance on Western laws in the relatively new states of the region is perceived by some as lingering foreign intervention. This is why some states (including Afghanistan, Iran, Pakistan, Sudan, and Saudi Arabia) reinstated Islamic criminal punishments and why many Muslim scholars advocate Islamizing modern nation-states. Sayyid Quṭb (d. 1966) was a prominent Muslim Brotherhood intellectual who advocated for Islamic governance and was executed by the Egyptian government. Pakistan's highly influential thinker, Abū al-ʿAlá Mawdūdī (d. 1979) argued for the necessity of an Islamic state. Iraqi Shīʿī jurist Muḥammad Bāqir al-Ṣadr (d. 1980) expounded on the role of Muslim jurists in Islamic states, which later influenced the Iranian constitution and popular ideas about Shīʿī governance. Al-Ṣadr was the author of an important work on Islamic economics (*Iqtiṣādunā*), whose proposals for an Islamic alternative to capitalism and communism extended throughout the Arab world. His political writings influenced the Iranian revolution and he was active in forming an Islamist party in Iraq. The 1978–79 Iranian revolution provoked renewed attention to the

role of Muslim jurists in modern states. Ayatollah Khumayni (d. 1989) elaborated, advocated, and implemented a theory (*wilāyat al-faqīh*) that gave Muslim jurists authority over political and governmental life. In contrast to this official role for jurists, many other Muslim-majority states include a reference to Islamic law as a source of law in their constitutions, without thoroughly defining who will implement Islamic law.

The primary focus of Islamic legal change in the twentieth century had been family law; this arena is the principal focus of Western/colonial attention to and criticism of Islamic law. Turkey issued a family law code in 1917 that was based on the four orthodox Sunnī schools of law, as well as some opinions from extinct or minority legal schools. Other states followed the Turkish model, with Egypt issuing its personal status laws in 1929, Syria in 1953, and other countries soon thereafter. These family law codes not only selected legal rulings from across several legal schools, they also introduced reforms – particularly in limiting polygyny or the divorce prerogatives of men. One of the more well-known legal reformers is ʿAbd al-Razzāq al-Sanhūrī (d. 1971), who led the drafting of the Egyptian Civil Code (1948/9) and the Iraqi code (1951) and participated in the drafting of codes for neighboring states (including Iraq, Syria, Jordan, Kuwait, and Libya). Sanhūrī earned two doctorates from the University of Lyon, was the dean of both an Egyptian and an Iraqi law school, and held several government positions. Sanhūrī sought to modernize Islamic law and develop a modern legal system that would benefit from comparative analysis, but emphasize Islamic values.

In the modern era, the traditional legal schools became less influential than they once were. The Ḥanafī school is prevalent in Turkey, the Levant, and parts of South Asia; Mālikīs are present in North Africa and small parts of the Gulf; the Shāfiʿī school is dispersed in Indonesia, Malaysia, southern Egypt, the Gulf, East Africa, and the Levant; Ḥanbalīs are concentrated in the Gulf. (The Ḥanbalī school spread in the eighteenth century as a result of the Wahhabī movement in the Arabian Peninsula.) Contemporary Islamic legal changes are most evident in the scholarly writings and legal decrees of reputed jurists, as well as the judicial decisions and statutory legislation of some Muslim-majority states. The sociopolitical role of the jurisconsult (i.e., *muftī*) has broadened in the modern era, as a result of the institutional structure (*dār al-iftāʾ*) that supports the issuing of legal decrees, as well as the emergence of print and other media to disseminate legal opinions. More recently, Sunnī jurists have attracted followers through their issuing of legal decrees, including on Internet sites such as Islam Online, www.islamonline.net. Several contemporary Muslim intellectuals who speak publicly about Islamic law are either exiled or living under complicated circumstances in their home countries; examples include the Iranian ʿAbd al-Karīm Surūsh, who lives in exile, and the formerly exiled Tunisian Rāshid al-Ghannūshī, cofounder of al-Nahḍah, the largest political party in post-uprising Tunisia. Still, some Muslim jurists have strong alliances with their governments.

Legal reforms of the nineteenth and twentieth centuries were incremental, as modern nation-states created courts that gradually extended their jurisdiction into areas of the law that had been administered by Muslim jurists. Just as the jurisdiction of Islamic courts narrowed to particular doctrinal areas (particularly family law), so too did popular understandings of 'sharīʿah' become synonymous with certain legal norms; rather than a tradition of professional juristic training and a set of jurisprudential methodologies, Islamic law came to mean a set of laws. Indeed, it is an irony of the contemporary Islamic revival movement that the state's cooptation of the previously independent judiciary is not the focus of resistance.

Growing communities of Muslims who are minorities in non-Muslim-majority states has generated interest in 'minority Islamic jurisprudence' (*fiqh al-aqallīyāt*). The Fiqh Council of North America has issued legal decrees encouraging the assimilation of Muslims in US civil and political society. The European Council for Fatwa and Research is similarly active in publishing legal rulings that meet the diverse and sometimes complex needs of Muslims living in non-Muslim societies. An example of these kinds of rulings is legal decrees permitting Muslims to serve in the armies of Western states.

Resistance (CE 2010–present)

While the colonial period formally ended in the mid-twentieth century, Western interventions and neoimperialism continue to shape the everyday practice of Islamic law. In the midst of uprisings throughout the Arab world, Muslim jurists played roles either in negating the validity of demonstrations (as in the case of state-appointed muftī Dr. ʿAlī Jumʿah's defense of the Egyptian regime in 2011) or in encouraging demonstrations (as in the case of "independent," Qatar-based jurist Yūsuf al-Qaraḍāwī's articulation of the legitimacy of regime change in 2011). A new genre of legal literature devoted to revolutions (*fiqh al-thawrah*) is emerging. Questions about Islamic constitutionalism or the role of Islamic law in public society continue to be debated.

Methodology of Orthodox Islamic Jurisprudence

Orthodox Islamic jurisprudence is *uṣūl al-fiqh*, which translates to "the principles by which Islamic law is derived" (from a set of normative Islamic legal sources). The two main textual sources of Islamic law are the Qurʾān and *sunnah*. Whereas *uṣūl al-fiqh* refers to the roots of Islamic law (or jurisprudence), *furūʿ al-fiqh* refers to its branches (or doctrinal law, both substantive and procedural). Jurisprudential texts discuss hermeneutic guidelines for interpreting and classifying the legal content of Qurʾān and *sunnah*, as well as the identification of consensus (*ijmāʿ*) and methods for analogical reasoning (*qiyās*). Legal reasoning (*ijtihād*) comprises a variety of distinct techniques for deriving legal rulings (Kamali, 1991). Most jurists classified legal acts into five basic categories – obligatory, recommended, permitted, abhorred, and prohibited. A significant distinction between Sunnī and Shīʿī jurisprudence is that the latter tradition considers Imāmī legal opinions as infallible legal sources. The differences of legal opinions between and within legal schools are produced as a result of distinct hermeneutic approaches and of dissimilar reliance on textual and nontextual legal sources.

In Islamic legal literature, *furūʿ al-fiqh* is where one finds legal opinions on a wide array of topics, commonly divided into ritual matters (such as purity, prayer, charity taxation,

fasting, and pilgrimage) and social relations (marriage, divorce, inheritance, sales, loans, partnerships, crimes, torts, and court procedures). Two types of *furūʿ* texts coexisted – the *mukhtaṣar* (abridged legal compendium) and the *mabsūṭ* (comprehensive commentary and explanatory legal compendium).

Conclusion

Beginning with the founding of a Muslim community in seventh-century Arabia, Islamic law has undergone significant and frequent changes. Actual legal practice has been infinitely varied, according to locality, legal school, and many other situational factors. Custom or socioeconomic circumstances often decide whether or not aspects of the law are applied. The application of the law to practical situations and the procedure of consulting scholars for legal opinions generate legal changes. The relationship between Muslim jurists and political structures varied according to time and place. Islamic law is both historically and normatively flexible.

Islamic Social Work: Hope and the Commitment to Change

Nada Eltaiba, The University of Western Australia, Perth, WA, Australia

© 2015 Elsevier Ltd. All rights reserved.

Abstract

There is a growing interest in religious and spiritual healing among social workers. Religion and spirituality have been the subject of discussions by many scholars and are increasingly considered an essential source of understanding about human beings and their ways of coping with psychological and social problems. This article addresses the concept of hope in relation to religious and spiritual healing in the Islamic texts, the Qur'an and the Hadith. The concepts of religion and spirituality overlap in the Islamic context and are used interchangeably in this article.

Introduction

There is a growing interest in religion and spirituality among social workers. This is reflected in the significant growth in the number of publications and the breadth of research on spirituality and religion in social work (Al-Krenawi and Graham, 2003; Eward R. Canda and Furman, 2010; El-Amin, 2010; Eltaiba, 2007; Furman et al., 2011; Graham and Shier, 2011; Seinfeld, 2012). An understanding of religion and spirituality is increasingly considered an essential source of insight into human beings and their ways of coping with challenges and difficulties. In social work, the interest in religion and spirituality is related to the increased attention to enhancing cultural competence including in the spiritual and religious realms. This is considered an ethical obligation for social work practice (AASW, 2000).

Religion and spirituality have found to enhance optimism, confidence, self-worth, and respect. Studies show that people become more religious when they encounter challenging experiences or are affected by psychological problems (Al-Krenawi and Graham; Edward R. Canda and Furman, 2010; Chen and Koenig, 2006; Graham and Shier, 2011; Kvarfordt and Sheridan, 2007; Seinfeld, 2012). In most cases, religion is significant in their lives at the personal and the social level. People tend to cope better when they turn to religion to make sense of turmoil or to find hopeful insights.

The concepts of religion and spirituality are the subject of great discussion and are considered by many to be controversial. Some researchers, practitioners, and individuals experience difficulties differentiating between the two terms (Edward R. Canda and Furman, 2010; George et al., 2000). According to Canda, "Religions are institutionalised and organised patterns of belief, morals, rituals, and social support systems that have spirituality as their central concern." He further defines spirituality thus: spirituality involves the search for a sense of life purpose, meaning, and morally fulfilling relationships between oneself, other people, the universe, and the ultimate ground of reality (Canda, 1999: p. 12). Both religion and spirituality are personal and share sacred core.

For Muslims, religion and spirituality are considered, in essence to be the same; the concepts do not occur distinctly from each other (Hyman and Handal, 2006). Both religion and spirituality must be considered within a collective context and framework. In the following discussion, the term religion is used to include spirituality and religiosity. The concept of religion is considered to incorporate spiritual aspects, beliefs, values, acts, and symbols that comprise Islam (Eltaiba, 2007).

Religious values and practices for Muslims incorporate various social, political, and spiritual activities. For the majority of Muslims, religious beliefs have a fundamental place in their interpretation of and coping with different problems. For example, research has found that there is a strong inclination among members of Muslim societies to express themselves using religious discourse and toward combining spiritual healing with other approaches when dealing with difficulties. This includes referring to the Islamic texts, the Qur'an and the Hadith (Al-Krenawi and Graham, 1999; Eltaiba, 2007).

Islamic texts are part of the daily life of most Muslim people. The Qur'an for Muslims is considered the ultimate book of the Islamic religion (Horrie and Chippindale, 2003). The Qur'an has organized values for all aspects of human life, including health and healing values. The Qur'an provides Muslims with guidance on what to do and what not to do in order to be close to Allah. Consequently, individuals may be kept from some problems or be enabled to deal with these problems more constructively. There is a belief in Islam and among Muslims that the Qur'an has healing powers (Al-Krenawi and Graham, 1999; Eltaiba, 2007). The power of healing of the Qur'an is stated as follows: "And We send down of the Qur'an, that which is a healing and a mercy to the believer" (Qur'an 17:82).

The Hadith, books of 'prophet Muhammad's traditions and sayings,' is considered another main source that explains how the Qur'an can be applied to Muslim lives in order to lead the best life possible and helps people to understand problems according to the Islamic faith.

Islamic texts are recognized as providing a rich context within which to interpret difficulties. Understanding the options for coping processes that these texts provide is valuable and necessary for social workers practicing in Muslim communities. Some of the central concepts with which social workers need to be familiar are hope and the obligation to change.

Hope in Islam

Defining hope is challenging. It has predominantly been linked to expectations and the achievement of goals (Whitley, 2010). Hope comprises four components: the affective (e.g., trust, confidence, humor, and positive emotions); the cognitive (e.g., reflecting on past experiences, goal setting, planning, and

assessing the likelihood of success); the behavioral (e.g., motivation and personal activity); and the environmental (e.g., availability of resources, health care, and relationships) (Schrank et al., 2008).

The promotion of hope in association with religion is seen as important in the journey of coping with difficulties. Hope, for example, is identified in mental health literature as a significant aspect of the recovery process and it is strongly manifested in the recovery discourse (Anthony, 2003; Bonney and Stickley, 2008; Whitley, 2010). Recovery from mental health problems is linked to hope, which provides a strong foundation to recover. In addition, hope is seen to speed the recovery process and aid in sustaining it.

Likewise, hope is an important theme in the Qur'an and the Hadith. It is presented as a feeling of relief and comfort despite facing difficulties or crises. The believer expects that the situation will ease and things will be better; they will never give up and will keep going. In that sense, hope will keep motivating the person to work, be determined to achieve, and to be in a better place in their life.

In the Islamic context, hope means to have gratitude that there will always be a possibility of overcoming problems and difficulties. Hope helps people to tolerate and overcome life's challenges and catastrophes. Without such hope, things would be much harder for those suffering. In the Qur'an and the Hadith, the difficulties in life are seen as being followed by periods of relief. The Qur'an states

> So, verily, with every difficulty, there is relief: Verily, with every difficulty there is relief.
> Qur'an 94:4, 5

This also was confirmed by the teaching of the prophet as the Hadith states: "Prosperity comes after agony and sorrow; and every ordeal is followed by easy circumstances" (Nawawi and Abbasi, 1980), endurance of suffering is rewarded. Human beings are expected to strive to do their best in order to cope with problems. Facing challenges is part of the journey of human life. These challenges are a trial from Allah and human beings are expected to suffer through the process. The Qur'an says:

> Or do you think that ye shall enter the Garden of (bliss) without such (trials) as came to those who passed away before you? They encountered suffering and adversity and were so shaken in spirit that even the Apostle and those of faith who were with him cried: 'When (will come) the help of God?' Ah! Verily, the help of God is (always) near.
> Qur'an 2:214

As hope is part of being a believer, losing hope is forbidden in the Islamic tradition. Not having hope and not being motivated to work and change is considered to be against the teaching of the Qur'an and the Hadith. The Qur'an says

> And never give up hope of God's soothing Mercy: truly no one despairs of God's soothing Mercy, except those who have no faith.
> Qur'an 12:87

There is an acknowledgment in Islamic tradition that regret and feelings of guilt may lead to a psychological state in which people become affected by some psychological problems. These feelings might create some difficulties for the person, which prevent them from looking into the issues of their life in a positive manner. This will also cause the person to be less hopeful, less accepting, or less motivated. Learning about the forgiveness of Allah, as it is represented in the Qur'an and the Hadith, is considered a way of coping with these feelings. This is especially so in cases where individuals feel guilt associated about committing actions that go against religious commands or if they feel they are not deserving of good. In the Qur'an, believers are ordered not to be demanding on themselves, as there is a space where these misdeeds are forgiven:

> O my servants who have transgressed against their souls! Despair not of the Mercy of Allah' for Allah forgives all sins for He is oft-forgiving, Most Merciful.
> Qur'an 39:53

On the other hand, the feeling of hope is a sign of a strong relationship with Allah and it is based on the belief that Allah will respond to people when they ask for help. This is stated in the Qur'an in the following verse:

> And never give up hope of God's soothing Mercy: truly no one despairs of God's soothing Mercy, except those who have no faith.
> Qur'an 12:87

One of the important features of the loss of hope as forbidden in Islam is that of harming of the self. Self-harm is not allowed in the Islamic tradition; Suicide is considered a sin in Islamic teaching. If a Muslim does harm themselves, he or she will not be granted heaven after death. The Qur'an says:

> Nor kill (or destroy) yourselves: for verily God hath been to you Most Merciful!
> Qur'an 4:29, 30

A wish for death is also considered forbidden in Islamic tradition, as the Prophet said, "None of you should wish for death because of a calamity befalling him" (Sahih Bukhari: vol 8, p. 202). While self-harm or wishing for death is not allowed, the individual, if in pain that is too hard to endure, can pray by saying, as the prophet instructed "O Allah! keep me alive as long as life is better for me, and let me die if death is better for me" (Sahih Bukhari: vol. 8, p. 202).

Hope in Islam is associated with an important theme, which is the *Tawakul*, or the reliance on Allah, and the commitment to change. *Tawakul* is important in Islam and means sincere trust in Allah in all aspects of life. It is also about the belief that everything refers to Allah (Ibn Kathir, 1966). *Tawakul* means the recognition of the limitations of human beings and acknowledging that illness and healing are in the hands of Allah. The belief that Allah is the source of everything supposedly will assist the person with mental health problems to have trust and depend on God in lifting the burdens of their

illness. The Qur'an states, "And on Allah let all men of faith put their trust," and "Sufficient is God for me! in him trust those who put their trust" (Qur'an 14:11; 39:38). *Tawakul* is associated with holding on to the hope that Allah will definitely make things easier for individuals who put their trust in Him.

Trust in Allah or *Tawakul* requires safeguarding Allah's commands or what is called in Islam, *Taqwá*. These concepts are associated with hope and prosperity. Trust in Allah and the safeguarding of his commands will consequently result in achieving goals and relieving distress. The Qur'an says:

> And for those who fear Allah, He (ever) prepares a way out, And will provide for him from (a quarter) whence he hath no expectation.
> Qur'an 65:2, 3

In the Muslim relationship with God, Allah is the creator and the human being is the creation of Allah. Oneness is the basic element in the connection with Allah. The role of the human being is to submit to the power of God and to worship him alone. The importance of this relationship is frequently emphasized in the Qur'an and the Hadith. An example of this concept is identified in the following verse, "He is Allah the One and Only" (Qur'an 112:1).

The belief that Allah is the source of everything and anything, and that Allah's power and knowledge is the ultimate power, forms the central understanding of this relationship. Everything is from Allah, things happen only with his permission, and if he wills them. This notion is frequently identified in the Qur'an and the Hadith. Distress, illness, poor health, and any other difficulty in life are all the result of Allah's will. In this relationship, God is the one who has the ultimate supremacy. Allah's power is emphasized, as the following verses states:

> To Him is due The Primal origin of the heavens and the earth When He decreeth a matter He saith to it: 'Be'. And it is.
> Qur'an 2:117

In this sense the truth about human beings, including their social or psychological problems, are all within Allah's knowledge. For example, human interpretations of what might be the source of their mental health problems are only endeavors. They are only possible interpretations, which might be right or wrong. Humanity's knowledge is limited within the knowledge of Allah. This concept that is frequently mentioned in the Qur'an, strongly indicates the vulnerability of humans in their relationship with Allah the creator and the one who has ultimate knowledge: "It is Allah Who knows, and ye who know not" (Qur'an 3:66).

Hope and Change: Transferring the Self

Hope is connected to dedication to making efforts to change. There is a strong correlation between hope and change. Hope will increase the motivation of a person to look for change and, furthermore, when they achieve any change, they will have more hope.

To achieve change in human life a person must begin this change within themselves. Change within requires the person to commit to modifications in their emotional and cognitive process. It is about defining goals, organizing a plan for the change, being positive, and becoming an active participant in the change process. The Qur'an states,

> Verily never will Allah change the condition of a people until they change it themselves (with their own souls).
> Qur'an 13:11

It is also acknowledged that this change requires building knowledge and commitment to transformation of the self.

Change requires the search for knowledge, and searching for knowledge is seen as a continuing process of exploration. Humans are required to be flexible, to change their interpretations, and to accept new information. All of this is within the oneness of their relationship with Allah. The Qur'an says, "Verily in that are Signs for those who reflect" (Qur'an 30:21). Individuals are responsible for seeking knowledge about the possible causes of their disorders, for ways of coping, and for help. Knowledge is used to make sense of a problem and to find practical solutions. People with psychological problems, for example, are encouraged to consult with experts and practitioners in different professions to increase their awareness of the problem and to develop strategies to alleviate their problems.

Strengthening the Relationship with Allah

One of the main ways to enhance hope and change is for the person to commit themself to rebuilding a strong relationship with Allah. Change within requires the person to strengthen their relationship with Allah. This is achieved by increasing their submission to Allah, their repentance to Allah, their reliance on Allah, and by being patient. It also requires looking for practical steps to overcome problems. Building their relationship with Allah and strengthening their spirituality will motivate the person to change and to have hope for the positive outcomes related to working on the self, seeking help, and changing one's actions.

In terms of strengthening one's relationship with Allah, it is considered that Allah's will is the essence of understanding the causes and the help that is being sought. The notion of building one's relationship with Allah is rated highly in Islamic tradition: the Qur'an says

> O ye who believe! Endure, out-do all others in endurance, be ready, and observe your duty to Allah, in order that ye may succeed.
> Qur'an 3:200

Seeking Allah should not only to take place during the easy times but also during the difficult and distressful times, during the misfortunes in life and the hardships encountered. The notion is that the difficulties in life are trials or blessings to prevent worse things from happening.

A person's relationship with Allah can also be strengthened by praying, fasting, giving to charities, *Dua* (prayers), and reciting the Qur'an. All these activities are supposedly ways to enhance hope and increase the change within people with mental health problems. While looking for help, the person is expected to be patient and tolerant. This is emphasized in the Qur'an:

> O ye who believe! Seek help in steadfastness and prayers. Lo Allah is with the steadfast.
> Qur'an 2:15

Saber, as well as being patient and tolerant, is important for succeeding in the journey of recovery. Making *dua* or asking Allah for help is another important way to foster this relationship with Allah as the Qur'an says,

> Call on Me. I will answer your prayer.
> Qur'an 40:60

Looking for practical help, whether it is from professionals or family, friends, and mentors, is encouraged in Islamic tradition as one of the responsibilities of the person who encounters difficulties. It is a method of making changes and acquiring hope. The person will seek help through these avenues, while at the same time having hope and trusting in Allah. Two of these avenues might be social networking or professional help. In relation to social networking, the person is encouraged to maintain their connections with family, neighbors, and the community. The Prophet emphasized that by saying "… And Allah will aid His slave so long as he aids his brother…" (Nawawi and Abbasi, 1980). Members of these groups are obliged to provide support and they will be rewarded for doing so. The duty of the family and community is to provide information and resources that the people in need can access (Ahmed, 1998; Kinzie, 2000). For example, looking for scientific treatment for problems related to health is part of the responsibility of Muslims. One of the basic notions in Islam is that there is a cause for illnesses and Muslims are commanded to look for treatments for their illness. They are also encouraged to integrate medical and physical healing as well as psychological and spiritual healing (Kinzie, 2000). There is always hope that medical and/or scientific developments will lead to treatment options being available in the future. The seeking of medical treatment is encouraged by Islamic tradition and this treatment should be sought from anyone who possesses scientific knowledge or who can provide support, regardless of their own religious or spiritual beliefs. The Prophet Muhammad explained to his followers in the Hadith,"There is no harm of any treatment as long as it is beneficial to human being" (Sahih Bukhari: vol. 7, p. 362).

Keeping Balance

In their journey to change within and on the practical level, people are encouraged to keep balance in their lives. In the Islamic faith, the concept of keeping balance in life is a crucial aspect of coping. This concept means that the person needs to pay attention to all aspects of their life, so as to not to emphasize one aspect at the expense of another. Balance means that the person pays attention to their physical, spiritual, social, and intellectual needs. The importance of this concept in the Islamic tradition is emphasized by its mention in the Hadith: "There is share for your eyes, share for your own self, share for your family" (Sahih Muslim: p. 564).

It is important to take care of the human and everyday needs of the lives of individuals, but also not to omit or overlook spiritual needs. Ansari notes that the concept of *nafs* (self, or living entity) is considered, in Islamic philosophy, to be a mixture of the biological, the psychological, and the spiritual (Ansari, 2002). All these parts need to be nurtured. Examples of doing this might include regular exercise (such as weekly), visits to family, relaxing with friends, and being industrious in some kind of work (whether paid or unpaid). This concept is stressed in many occasions in the Qur'an and the Hadith, where there is an emphasis on maintaining balance in order to reach the balance of the *nafs*. In the Hadith, Muslims are encouraged to balance the needs of the self and the needs of others around them, such as family members. The believer needs to revise his life frequently in order to make balance in everyday activities, family, work, and relationships.

Implication for Social Work Practice

Social workers for both Muslims and non-Muslims can utilize these concepts of hope and change when working with clients from Muslim backgrounds. It is important that they are aware of hope and change within the context of Islamic philosophy. This is because these concepts can play a major role in motivating clients to work actively on problem solving, help seeking, and coping with various life difficulties.

Before talking with clients about these the concepts of hope and change, social workers need to first explore with the client their level of religiosity, spirituality, and willingness to talk about these concepts. This provides a safe environment for clients to speak. Social workers can then explore these concepts, asking what hope and change mean for them, how these concepts are related to their faith, and exploring to what extent the clients relate these concepts to their problems, social workers can also help clients to create a plan to strengthen their spirituality, to help them better cope with difficulties. Social workers and clients can together look into the relationship between hope and change.

In summary, the concepts of hope and the changing of the self are important values of Islamic religion and spirituality. They are crucial parts of the journey of individuals to accessing the help of social workers. Hope and change help Islamic individuals to make sense of disorder, and motivate them to look for ways of coping with their problems. As a result, social workers can use these concepts to assist Islamic clients to enhance their lives, to be motivated to strengthen themselves internally, and to look for resources to help them to deal with their problems – professionally and within the community.

Isms and History

Abstract

This article examines the role of *ism*-categories in history and in history writing. Very often casually used, *isms* permeate not just scholarly work but also everyday parlance – and yet neither outside of nor within academia do people often ask exactly why and how we use them. What do they mean? What types of *things* are they supposed to encapsulate? The article presents an overview of some of these issues through references to a chronologically and thematically varied spectrum of sources; unveils some significant early modern instances of *isms*; and reflects on how history is written *now*. Departing from a widespread epistemological approach to the study of history, it is here suggested that to employ *isms* can be useful in the attempt to understand the past, its languages, ideas, people, and systems of beliefs. Indeed, the following pages show how a less essentialist use of *isms* might provide new meaningful readings of past thoughts and events. Finally, by rethinking the role of the (intellectual) historian in dealing with *isms*, some methodological considerations on the practice of history writing as an act of observation as much as one of creation will also be advanced.

Introduction

The *Oxford English Dictionary* (OED) defines an *ism* as "[a] form of doctrine, theory, or practice having, or claiming to have, a distinctive character or relation". It also points out that *isms* are "chiefly used disparagingly" (*OED*, "ism, *n.*"). Above all, from the *OED* we learn that *isms* refer to the following units of meaning:

1. nouns of action where the suffix 'ismòs' derived from verbs in 'izein' indicates a thing done which is 'rarely concrete' (e.g., 'agonism', 'baptism', 'criticism');
2. words that express 'action or conduct of a class' of people (e.g., 'heroism', 'patriotism', 'despotism');
3. nouns applied to 'the condition of a person or thing' (e.g., 'barbarism', 'anomalism', 'parallelism');
4. names of 'a system of theory or practice' – often named after a person, subject, or object: e.g., Cartesianism, Kantism, Poujadism, Thatcherism – related to the 'religious', 'ecclesiastical', 'political', 'philosophical', 'social' spheres (e.g., 'Arminianism', 'Buddhism', 'Calvinism', 'Catholicism', 'Chartism', 'Liberalism', 'Machiavellism', 'Epicureanism', 'Positivism', 'Radicalism');
5. 'class-names' or terms describing 'doctrines or principles' (e.g., 'altruism', 'feminism', 'universalism'); and
6. terms 'denoting' linguistic characteristics (e.g., 'Americanism', 'Latinism', 'Orientalism', but also, e.g., 'archaism', 'colloquialism', 'witticism') (*OED*, "-ism, *suffix*").

This dry taxonomy is enlivened by some – mainly negative – historical examples that detail how *isms* and their users have been regarded since the eighteenth century. A telling sample of various social mind-sets and literary conventions comes from a letter dated 4 November 1789 where Horace Walpole reproached his interlocutor for his tendency to "squabble about Socianism, or some of these isms" (*OED*, "ism, *n.*"). Twenty-two years later, in a display of filial disaffection Percy Bysshe Shelley contemptuously proclaimed: "He [his own father] is nothing – no 'ist', professes no 'ism', but superbism and irrationalism" (Hogg, 1858). More cheerfully, in October 1820 in *A Letter to M. Allen* Thomas Carlyle stated: "I expect much pleasure from talking over old bygone things, from discussing Spürzheimism [Spürzheim was the founder of phrenology], Whiggism, Church of Englandism, and all other imaginable 'isms'." On a harsher note, the issue of *Fraser's Magazine for Town and Country* from June 1840 – targeting socialism and Owenism – unsympathetically declared that "[a]ll the untidy *isms* of the day shall be dissipated". In general, in nineteenth-century Britain it was believed that *isms* had spread from France as a result of the French Revolution (Cuttica, 2013). As for French views of *isms*, in 1921–22 Marcel Proust sarcastically dismissed the famous French diplomat Talleyrand as "one of the inventors of dilettantism, of I couldn't-care-lessism ['je m'enfichisme'], of many words in 'ism' now in fashion with our little snobs" (Proust, 1954). Another French literary doyen, Philippe Sollers, had one of his fictional characters mull over "[a]narchism, cubism, surrealism, communism" and scathingly remark that "'isms' after all give the impression of having been fabricated in order to hide the dawn of new names" (Sollers, 1983).

If *isms* flourished after 1789, in the early modern period it was the adjectival forms 'ist' and 'ian' and their derivative nouns 'ists' and 'ians' to be more commonly employed. *Isms* were applied as convenient shorthands like in the case of 'Arminianism' in seventeenth-century English political and religious discourse or when describing the thought and/or activities of one person from whom a movement or group of ideas took their origins (e.g., 'Hobbism'). Nowadays, it is often assumed that *isms*, which abound not only in political jargon but also in sociological, juridical, and journalistic language, constitute technical words, which the specialist is supposed to decode for us. Implied in this view is the distinction between common language as it is utilized by people in their daily interaction with the world and a more intellectually subtle conceptual use.

Searching for examples of the first kind, that is of how *isms* are present in everyday parlance, we find that on 9 August 2010 in an article published in the Italian daily *La Stampa*, Alberto Guareschi, son of the famous Italian journalist, cartoonist, and humorist Giovannino Guareschi, said that his father "was

against all 'isms', fascism, communism […] and he made use of the pen as a weapon, writing and drawing. He never took himself too seriously and his self-mockery made him closer to his readers" (Ferrari, 2010). This statement is significant in that it reveals a die-hard conviction that *isms* are not only the opposite of irony, but that they encapsulate the ideological poison whose lethal effects caused the tragic events, which occurred in the twentieth century. To confirm this view stands none other than Joseph Goebbels who referred to communism, fascism, Catholicism, and liberalism as "lies big enough to be believed" (Newbury, 2010). However, it can be said with reasonable confidence that positive (or, at least, neutral) connotations are generally attached to artistic movements such as Expressionism, Symbolism, Cubism, and Surrealism.

Other *isms* might be perceived as less dangerous, but they are still capable of arousing vehement reactions. Among these is intellectualism, which is identified with the practice of turning simple things into complicated matters. Intellectualism is despised as the opposite of good and matter-of-fact (hence healthy) conduct. Confirming this diagnosis is the case of the philosopher Edmund Husserl who in 1935 predicted that he would be accused of rescuing "an intellectualism which loses itself in theories alienated from the world, with its necessary evil consequences of a superficial lust for erudition and an intellectualistic snobbism" (Husserl, 1970). Husserl's observation proved tragically accurate: the Nazis made of 'antirationalism' and 'antiintellectualism' two explicit touchstones of their propaganda.

To be a source of heated disputes does not prevent *isms* from being successful: barbarism – to be found in Immanuel Kant's *What Is Enlightenment?* (1784) – and Orientalism – rocketed to academic stardom thanks to the greatly influential as well as highly divisive book on Western attitudes to the East written by Edward W. Said (1978) – are only two examples among a plethora of terms frequently used by the literati. It is also important to consider that there are *isms*, which are marked by the *anti* prefix. In this regard, the central question is whether it is plausible to adopt a polemical term such as anti-Americanism in a scholarly context. Obviously, this type of *ism* has derogatory connotations, which might impede a critical analysis of a phenomenon or set of ideas, and thus exclude debate. However, at other times the category can be legitimately used by scholars studying certain mind-sets, views, or policies (e.g., anti-Americanism in the context of the Cold War).

Scholars and Isms: Antipathy at First Sight

Despite their recurrence both in common parlance and in a good range of intellectual fields, there are very few studies that attend to *isms* (Williams, 1983; Quinion, 2002). One exception is A. London Fell's work on the major *isms* of early modernity and modernity (London Fell, 1996). Interestingly, London Fell started off by pointing to the numerous "forms of ideology expressed as 'isms'" thriving in the US during the fiery political debates of the 1990s between Republicans and Democrats. The then President Bill Clinton accused his opponent Newt Gingrich of unduly inciting 'rivalry' between conservatism and liberalism. For London Fell such a public interest in *isms* showed that what in the nineteenth century had been 'endemic' had by then become 'epidemic'. Myriad terms ending in *ism* could be found not just in the public discourse and the media, but also in a wide spectrum of academic disciplines from the history of art to philosophy and legal-political thought. More worryingly, historians' misuse of *isms*, according to London Fell, had led to sundry anachronistic interpretations of the past. For this reason, he adopted a – loosely conceived – deconstructionist technique to these "problematical 'constructs'", so as "to exploit" and "to explode" them (London Fell, 1996). Behind his anti'modernistic' deconstructionist project lay what London Fell called an attempt at "de-Hegelianizing" the welter of "anachronisms [sic] and ideological 'isms'" that have dominated scholarship on the modern state in the last two centuries. Viewing them as 'artificial academic devices' disconnected from the historical texts they purported to analyze, he astringently declared that 'to apply the suffix 'ism'" implies a large degree of scholarly blindness in that it obfuscates one's 'perception of a problem'. In consequence, this process 'needs to be *dis*pelled'.

In summary, if London Fell was right to argue that to study history through *isms* is open to pitfalls, it is also true that to use *isms* does not always correspond to invoking a quasiHegelian mystique of development. Rather, it means to advance a more fragmented reading of ideas in a given *historical* context with the platitudinous but fundamental goal of communicating knowledge to modern readers. It also means to accept that the historian is inevitably caught in the whirlwind of his/her time's intellectual activity, scholarly fashions, and cultural interests, which shape the direction of his/her research. If warning against anachronisms superimposed on historical sources and presentist interpretations of them is fruitfully pursued by people like London Fell, it has nonetheless to be observed that his type of approach presupposes that original texts and meanings exist, and that as such they can be recovered thanks to the *oracular* voice of the historian.

Harro Höpfl is the only theorist to have dealt systematically with the practice of using *isms* in historical and philosophical scholarship, and with the ensuing methodological problems (Höpfl, 1983). Focusing on etymology, Höpfl argued that *ism*-formations did not express the content of a doctrine or body of ideas. In their original Greek form 'ismòs', *isms* served as derogatory terms with which to define heretical, unorthodox, or false beliefs held by one's adversaries, and to characterize their conduct as much as their way of being. Subsequently, *isms* played a role in 'the construction of developmental histories' to define 'forces and agencies' behind social progress or change as well as to explain such histories in a more accessible fashion within a polemical context. Therefore, they came to represent more than simple labels for people's creeds: they expressed 'agents and causes'. In light of this evolutionary trend, Höpfl provided a series of 'genealogical' units with which to classify *isms*:

- those denoting the conduct or practices of a group;
- those generated in doctrinal and politico-religious contexts of conflict;
- those born out of politico-intellectual disputes since the nineteenth century;
- those adapted to scholarly use from their original polemical use;

- those specifically created for scholarly purposes; and
- those first employed by scholars but afterward taken up in common parlance.

Less neutrally (and a little too reductively), Höpfl asserted that *isms* serve to create 'a subject-matter for oneself'. Their popularity stems from the fact that a precise definition of what they mean is not required. Instead of being seen as a problem of synthesis, they should lead their users to 'a pause of reflection' in order to specify what one is referring to by them. This method is easier to pursue, according to Höpfl, when the referent is a set of doctrines instead of a phenomenon (e.g., 'fascism, communism, colonialism, leftism, pacifism, individualism, collectivism'). This is allegedly so because in the former case the category entails a process of self-identification on the part of the actors involved, while in the latter instance one has to confront the impossibility to grasp historical phenomena by dint of a simple *ism*. To remedy this last problem, Höpfl concluded, it is not sufficient for scholars to declare what is it they mean by their *ism* since this is tantamount to highlighting one aspect to the detriment of a larger range of components pertaining to the occurrence or circumstances under scrutiny (Höpfl, 1983).

Much more trenchantly, the founding father of the history of ideas, Arthur O. Lovejoy, had warned that *isms* are "trouble-breeding and usually thought-obscuring terms, which one sometimes wishes to see expunged from the vocabulary of the philosopher and the historian altogether" (Lovejoy, 1936). By the same token, Nicholas Henshall proclaimed that to study early modern political history implies to dispense with "a series of early nineteenth-century 'isms', which still obscure the differences between early modern consciousness and our own". According to Henshall, terms like "'liberalism', 'socialism', 'communism', 'nationalism' and 'absolutism' met the needs of political and social polemic in the 1820s and 1830s", but they do not help historical recovery of the past. Henshall disparagingly argued that "[t]he beauty of 'isms' is that everything can be made to fit them": they are generalizations which are used as historical tools (Henshall, 1996).

Pace Lovejoy and Henshall (and to some extent Höpfl too), many abhorred *isms* are nevertheless endowed with sound explanatory power and, therefore, can be used to describe portions of political thinking, social life, and economic trends expressed in various mediums in the past across the world. In this respect, Höpfl's approach whereby there are "three sorts of -isms which, at least in the hands of careful users, occasion no particular difficulty" – that is, *isms* accepted by those grouped under a category; *isms* referring to stances in a specific debate; and *isms* created 'ad hoc' to speak of "some determinate doctrine already identified independently of –isms" – is more incisive and deserves our attention (Höpfl, 1983).

As for the first remark, it is worth pointing out that the criterion of self-identification (on the part of a group of presumed adherents) as determinant in establishing the validity of an *ism* can hinder the work of the historian in that it assumes that to use an interpretative category to describe something in the past, that same category had to exist then. Such a view restrains the creative element informing history writing. In fact, if applied with due caution and awareness of their conventionality, *isms* can serve as interpretative torches with which to throw light on a more or less coherent plurality of ideas formulated at a certain time in a specific historical milieu within a more or less wide array of texts. Thus, one can reasonably adopt 'radicalism' (a nineteenth-century coinage) to refer to "radical moments of actions devoid of a programmatic radicalism, that is the development of radically pragmatic responses under the sheer pressure of events and circumstances", to describe the situation in which many early seventeenth-century English Puritans thought and acted (Davis, 2007).

With regard to Höpfl's second point on *isms* to be found in intellectual debates as objects of controversy or weapons with which to attack one's adversaries, it is necessary to consider some historical examples detailing the first appearances of some of the categories most frequently mentioned in the scholarship. This way of proceeding will provide a unique illustration of how *isms* played a decisive role in early modern polemics. It will also show that they established the meanings of concepts or currents of thought which were to rise to prominence in the nineteenth and twentieth centuries. Thus, searching for early instances of *isms* (notably, in the English context) we find that Machiavellism, Hobbism, Jesuitism, fanaticism, and a few others were fairly common both as ideological markers in political and religious controversies, and as labels with which to identify sets of ideas, principles, and patterns of behavior.

Isms: Historical Explorations

During the Elizabethan and Stuart eras, 'Machiavellism' appeared as an abusive epithet in the works of authors such as Thomas Nash (1593), George Downame (1603), Thomas Morton (1606), Andrew Willet (1607), Robert Bolton (1631), and William Burghley (1675). This might not come as a surprise, given the troubled pedigree of Machiavelli's doctrines and their impact on European political theory, and practice. And yet knowledge of this fact is a far cry from providing a thorough account of its fortunes. In fact, as Enzo Baldini has underlined, Machiavellism is an 'ambiguous and difficult-to-seize' term. By and large, it indicates 'theoretical arguments and political conducts' which throughout the centuries have directly referred to the Florentine's works. However, it has also been identified with all kinds of unscrupulous behavior and has often been equated to the paradigm of 'reason of State'. As a result, we can say that while 'Machiavellian' has to do with the theories elaborated by Machiavelli himself, 'Machiavellism' denotes a rearticulation of these theories in another historical context. This process includes translations and interpretations of his writings pursued in a more or less faithful way. In addition to this distinction, we have the terms 'Machiavellic' and 'Machiavellist': the former is employed in common parlance to refer to cunning and untrustworthy conduct (with an emphasis on plotting and dissimulation); the latter points to a disciple of Machiavelli, that is one who puts into practice his teachings without any moral scruple but with the exclusive aim of achieving personal gain. Finally, from the usage of the Florentine's works and ideas it has been possible to define Machiavellism as a 'political principle', whereby for a state it is licit to act in any way which is

conducive to its own benefit, especially if this is done in contrast to other states (Baldini, 2009).

Equally controversial albeit less enduring than Machiavellism was 'Hobbism'. If John Collinges argued that 'the world' was 'drunk with *Hobbism* & *Parkerism*' (Collinges, 1679), which he saw as nefarious political models, sundry thinkers associated Hobbism primarily with 'Atheism'. It appeared in this vein in the works of, among others, Anne Conway (late 1670s), Zachary Cawdrey (1681), Edward Stillingfleet (1681), William Sherlock (1687), Jeremy Collier (1689), and Richard Baxter (1689). Making people who were normally at odds with one another agree, 'Jesuitismus' – the bogeyman of sixteenth- and seventeenth-century English public polemics – was used by Laurence Humphrey as early as 1582, and was then to be found in the tracts of Francis Hastings (1600), David Owen (1610), and William Prynne (1655). 'Iesuitisme' appeared soon after (Georg Sohn, 1592; Christopher Bagshaw, 1601; Antoine Arnauld, 1602). It was vehemently attacked as the embodiment of scheming politics, ideological danger, and reprehensible moral conduct. Equally imbued with negative connotations and thrown around as a term of insult to describe doctrinally extreme positions typical of zealous and enthusiastic people was 'fanaticism', which can be found in the works of John Gaule (1657), Samuel Fisher (1660), John Corbet (1661), and Jeremy Taylor (1663).

Besides these fairly straightforward categories, one can point to others where flexibility of meaning and contextual changes engendered opposite definitions of the very same term. This was the case of 'patriotism', an instance of which featured in Thomas Urquhart's *Logopandecteision* (1653). In fact, whereas in the Tudor era the appeal to patriotism indicated support for the monarch, in the 1620s claiming to be on the patriotic side meant to manifest one's loyalty to the nation in contrast to the king. Patriotism served – sometimes simultaneously – opposite political projects and theoretical discourses (Condren, 2006). Furthermore, while 'Anglicanism' was not employed before the 1830s and 1840s, 'Anglianisme' had already been used in 1616 in Thomas Hanab's *Tessaradelphus* (Davies, 1992). Earlier still, attacking the jailed separatist lawyer Henry Barrow, the Episcopal archenemy of Puritans Richard Bancroft had complained about the 'new frenzy of Barrowisme' (1593) (Winship, 2009). In 1605 the nonconformist pamphleteer William Bradshaw had issued the laconically titled *English Puritanisme*, providing evidence that this other scholarly contentious *ism* existed in the Jacobean period (Bradshaw, 1605). Going back in time we discover that 'Lutheranysme' and 'Lutheranisme' as well as 'Caluinisme' were also part and parcel of early modern religious parlance, especially to signify two forms of 'schism' (Cuttica, 2013).

Having so far addressed two of the three points raised by Höpfl, it is now time to turn to the last and most relevant one: this has to do with *isms* created 'ad hoc' to speak of "some determinate doctrine already identified independently of –isms". To analyze this complex issue entails to do two things: first, to propose an inevitably limited but hopefully insightful classification of legitimate *ism*-categories which might help us to spot opinions, ideas, and moods present in a particular context; secondly, to examine what kinds of tools are deployed when interpreting the past, and, more specifically, to reflect on the practice of history writing from the methodological perspective of intellectual history. The next and final paragraphs deal with these two themes.

Rethinking Isms

If Lovejoy's claim that the historian's tool kit should be purged of *isms* is exceedingly harsh, his observation that *isms* "are names of complexes, not of simples" (Lovejoy, 1936) serves as a cornerstone of the present article. While one needs to be aware of the intricate network of theoretical avenues crossing history and of the difficulty of undoing them, it is nonetheless important to sketch a variegated multiplicity of language-patterns to be found on the canvas of this very history where they have been woven in different ways by men and women. This means that as neologisms signal a change in the perception of the world within a community, so the historian's invention of new *isms* helps to shed light on phenomena hitherto left unearthed and to dig out novel ideas sedimented in the past.

This is precisely the case of a recent article by Alexander Schmidt where the category of 'irenic patriotism' is employed to analyze 'different phases of irenic debate in the Empire' in the late sixteenth and early seventeenth centuries. By carving out 'irenic patriotism' as distinct from 'reason of State' or '*politique*' patriotism, Schmidt's research prompts important methodological questions on how to address paradigms of thought in a given historical context and on how to unfold features of past-discourses, which have not previously been taken into account (Schmidt, 2010; Cuttica, 2013). Schmidt's piece shows how *isms* display new objects of study, foster "new projects of knowledge" (Said, 1978) and unmask hermeneutical deception. Against arguments that they inevitably produce essentialist universalism, Schmidt's article confirms the didactically useful potential carried by *isms* in uncovering intellectual complexity. It also encourages us to break the unitary epistemological and interpretative model whereby the past is made of polar opposites (often expressed via misconceived and reductive *isms*).

Thus, the foregoing paragraphs enable us to formulate a different (less evolutionary than Höpfl's) proposal on *isms*, their *mode d'emploi* and their value. Six nonmutually exclusive categories emerge:

1. Cultural *isms*: they are employed in everyday conversation; they bring attention to certain phenomena, ways of speaking, habits, and mind-sets. In so doing, they often denounce, mock, and scorn. Hence they can hold an ethical dimension.
2. Descriptive *isms* (quasi-factual): they indicate specific governmental policies or strategies; programs implemented by groups with a particular intent; and individual behaviors informed by one main feature contained in the term composing the *ism*.
3. Derogatory *isms*: they are created to target people, groups, (e.g., sects, heretical fringes, rival parties, iconoclasts) and attitudes reputed to be abnormal or not in line with majority-thinking or dismissed as insignificant or disregarded as inferior.
4. Didactic *isms* (disciplinary-academic dimension): their purpose is to explain and, to a certain extent, to clarify

movements and ideas, historical periods and events, for an audience in education or part of the so-called educated-public.

5. Ideological *isms*: they refer mainly to the political, philosophical, and sociological spheres in that they denote grand narratives of thought and principles characterizing units of ideas interwoven with historical developments, especially in the nineteenth and twentieth centuries.
6. Technical *isms*: they are employed in scholarly work as a creative key with which to unlock hidden and/or neglected objects of study.

This way of proceeding is inspired by Ludwig Wittgenstein's idea of discourse as social practice and language in action. It applies to *isms* a sort of Wittgensteinian-linguistic cartography, an anthropology of language usage (Wittgenstein, 1963). This is not some kind of Borgesian utopia/dystopia whose ambition is to catalog every application of *isms*. Rather, it is an attempt to provide a picture of some central *ism*-uses. Despite being a work *ad infinitum*, this strategy might lead historians to recognize some cardinal points on their intellectual horizon and on that of the men and women they study. As a geographical map does not exactly correspond to the surface of the earth, so a schematic grid of *ism*-applications does not exhaust the entirety of all possible uses, but makes us more aware of the territory on which we move as investigators of the past. Exploring the ways in which *isms* might be adopted as well as how they fit with past terminology can be illuminating for the historian at pains to understand different theories, convictions, and prejudices.

In summary, what has been attempted above is no more than an outline of some important debates and tendencies concerning the use of *isms* in both public discourse and the scholarship. Having provided a broad picture of how various *isms* first emerged, of how they function in nonstrictly academic circles and of how they have been – and still are – treated by scholars, the article has then concentrated on the only work expressly dedicated to the study of *ism*-categories. Relying on Harro Höpfl's pioneering but now dated article, it has advanced some suggestions on how to make a more accurate and thorough use of *isms*. Now, these suggestions need to be connected to the activity of history writing (notably, from the viewpoint of intellectual history). To do so might further elucidate important aspects of the *ism*-question.

Isms and History Writing

If we take heed of several voices heard in this piece, we should get rid of *isms* altogether. This is due – we are told – to their reductionist configuration of the past of which they are supposed to give account. And yet the problem remains: what do we replace (many of the) *isms* with? What are the alternatives? And, if we identify them, why might these be in any lasting sense less problematic terms to become part and parcel of our scholarly vocabulary and methodological toolbox? To attempt an answer to these questions implies setting forth a few considerations on the *métier d'historien*. Practitioners of different disciplines within the larger framework of history writing disagree about *the right thing to do* with regard to method and often dismiss ways of proceeding which are not in tune with theirs as unfounded and sloppy. Instead of perpetuating this less than sympathetic trend and prescribe recipes for *the good scholar*, it might be more valuable to explore the field of research in which one pursues his/her work. In brief, the issue of whether *isms* should or should not be used might depend on how we look at our practice.

More specifically, it might have to do with what one thinks of the conventional devices historians deploy in order to put forward new readings of history. As terms like 'early modern', 'modern', and 'postmodern' help to divide into smaller units of time the chronological vastness opened before us, so the employment of *isms* helps to better grasp portions of the theoretical panorama of the past. Equally, classifications of past traces according to whether they are written or oral, documents or texts, public/official or private, erudite or popular, in a foreign language or our own, translated and, if so, by whom and under what circumstances, constitute indispensable lenses through which we bring into focus historical experience(s). All of these *tricks* – *isms* included – are the fruit of conventions, which can facilitate the study of history and strengthen our inevitably limited approach to it.

To address the complex issue of *isms* is also an attempt to rethink the conditions of knowledge available to the intellectual historian. In this sense, it is crucial to ask whether the (intellectual) historian is an antiquarian, a retriever of the past or a shaper of its cultural codes for consumption in the here and now. Is studying the past a reproductive endeavor or does it imply a creative effort? Should historical research be guided by the ideal goal of telling what *really* happened? Or, more humbly, should it consist in a quest for understanding through the fallible instruments at our disposal, the meanings of textual traces left behind on that horizon? If the task of the intellectual historian is to become aware of concepts and ideas nowadays accepted in an often uncomprehending manner, then to examine how *isms* are employed is not only justified but necessary. As an archaeologist excavating the past and bringing to life remnants of it, historians should not refrain from using languages, categories, and models which, while being respectful of the rhetoric of past authors, can communicate to modern readers a sense of what it *might have been like* back then (Cuttica, 2012).

This project entails an inventive effort on the part of the historian. It presupposes a practitioner willing to adopt a different pose before past-fragments left in, e.g., texts, documents, paintings: one that applies imagination and irony to the art of unraveling *and* narrating what went on in both the foreground and the background of historical experience. Moved by the aim of molding new ideas, images, or concepts so as to better capture events and actions, words and theories scattered on the often alien canvas of history, the intellectual historian carries out his/her activity more like an *artist* than like a scientist. As Brian Young put it, he/she is active and persistent 'in cultivating the artist's penetrating eye'. Shaped by "the idea of history as literature, and literature as history", intellectual historians are "uniquely sensitive masters of rhetoric (and entrepreneurs of the rhetorical repertoire rather than philosophers)" (Young, 2002). This profile suggests that, "historians,

like novelists, are makers of order" (Worden, 2001). It also reminds us that to use *isms* is integral to the enterprise of translating past utterances for twenty-first-century readers. In other words, to convey the past to an audience requires transmitting images in an intelligible way, and this is precisely what *isms* do by helping readers to see connections that might otherwise have remained obscure.

Conclusion

Might the (intellectual) historian thus be described as an *ismist*, as one cultivating the art of *ismism*, which may well, from time to time, involve not just the radical redefinition of existing *isms* but even the invention of new *isms*? If so, to operate within the methodological framework of intellectual history does not mean to a-priori proclaim whether *isms* should be used or strictly avoided, but to ask ourselves – as has been done in this article – how *history* has employed them; how we can understand them; and what use of them might be productive of new knowledge. When handling *isms* the intellectual historian acts, on the one hand, as somebody who traces their developments through successive epochs and multifarious contexts and, on the other, as somebody who carefully clarifies how he/she is managing them in his/her effort to illuminate and narrate the past.

This critical inquiry should conduce us to realize that *isms* are both the elaboration and the outcome of choices made at different times in history. This approach might also encourage us to think about the future of *isms*, notably of those that, faced with the incumbent global economic recession, have failed to provide solid answers to it (e.g., capitalism, neoliberalism, socialism, libertarianism). By doing so, we would keep alive the controversial but engaging history of *isms* and their practice.

Issue Evolution

Edward G Carmines, Indiana University, Bloomington, IN, USA

Abstract

The standard model of partisan change emphasizes the role of critical elections in bringing about dramatic and quickly realized changes in the party system. In contrast, the model of issue evolution focuses on more gradual and incremental change in the party system – change that is driven by issue competition among partisan elites, which eventually leads to a transformation in mass party alignments along the issue dimension. Thus, there are two characteristics that distinguish this model of partisan change. First, issue evolution presumes that most partisan change occurs gradually over a lengthy span of time, unfolding over several elections and perhaps decades instead of a single election. Second, the model emphasizes the role of partisan elites in initiating and leading political change. The crucial role of the mass electorate is to respond – or, more frequently, fail to respond – to the issue cues of partisan elites. The process of issue evolution, then, involves elite reorientation on the issue that eventually leads to mass issue realignment.

Issue evolution refers to a model of partisan change in which issue competition among political elites, often spurred on by political activists, gradually leads to a transformation in mass party alignments along the issue dimension. There are two characteristics that distinguish this model of partisan change. The first is the critical role played by elites. Unlike most models of elite–mass linkage political elites are not seen as merely responding to the demands of the mass electorate but as shaping and establishing the reputation of political parties on a political issue. The masses are seen as eventually reacting to these elite cues (MacDonald and Rabinowitz, 1987; Zaller, 1992). However, since it takes time for parties to establish a reputation on a political issue and for citizens to perceive and act on this difference between the parties, mass partisan change typically occurs gradually over a lengthy span of time. Ultimately, the transformation of mass party alignments occurs when the issue moves current voters to change their partisan identifications and biases the recruitment of new partisans.

The Standard Model of Partisan Change: The Critical Election Perspective

The standard model of partisan change was provided by V.O. Key in the 1950s (1955). His model of critical elections postulates that dramatic events can quickly transform the fortunes of political parties, leading to a realignment of the party system during the course of a single election. His account seems to fit almost perfectly the New Deal realignment. The Republicans, dominant in national politics since the 1860s, were held responsible for the Great Depression and, as a result, millions of voters deserted the 'Grand Old Party' and became Roosevelt Democrats during the 1932 presidential election. The New Deal realignment thus seems to be a case of partisan change that was both dramatic and quickly realized, resulting in the rapid replacement of an old majority party by a new one.

Criticisms of the Standard Model

Key's model of critical election realignments, especially as amplified in Burnham's *Critical Elections and the Mainsprings of American Politics* (1970), became the standard framework for understanding changes in the US party system. Despite its popularity and influence, however, several major criticisms have been directed at the critical election realignment perspective (Mayhew, 2002). In the first place, it has been impossible to specify exactly what constitutes a critical election. This vagueness has led to claims of realignment for virtually every recent presidential election (Bass, 1991). The generalizability of the theory has also been questioned since it is difficult to build a general theory based on a single historical case (Carmines and Stimson, 1989; Silbey, 1991). Finally, it has been argued that the critical election perspective overemphasizes short-term partisan change, while neglecting more gradual changes that extend over a long period of time (Carmines and Stimson, 1989).

The Issue Evolution Model

Carmines and Stimson (1981, 1986, 1989; also see Carmines and Wagner, 2006) have developed an alternative model of partisan dynamics which they refer to as issue evolution. Unlike the classic realignment model, it presumes that most partisan change occurs gradually and incrementally over a lengthy span of time, unfolding over several elections and perhaps decades instead of a single election. At no single point in time is partisan change necessarily striking but its culmination through time can leave an indelible imprint on the party system.

Most issues, according to Carmines and Stimson, lack the capacity to generate significant partisan change. This is because most issues have one or more of the following limitations: they reinforce the existing party alignment, they never capture public attention or they have effects that are entirely short term. It is only those relatively rare issues that transcend these limitations that have the capacity to lead to fundamental and permanent change in the party system. In other words, an issue evolution only occurs when a new issue emerges that cuts across the existing party–issue alignment, captures the public's attention for an extended period of time, and cannot be resolved in the normal policy-making process.

Carmines and Stimson (1980) put particular emphasis on the amount of cognitive processing required to deal meaningfully with a political issue as a critical dividing line between those issues that can and cannot lead to issue evolutions. Issues that are complex, technical, and obscure are not good candidates for issue evolution. Instead, if issues are to transform mass party alignments, they must be able to be understood at a 'gut' level, engaging the raw emotions of the citizenry.

Two basic aspects of an issue evolution are its structure and sequence.

The Structure of Issue Evolution

There are two main actors in issue evolution: partisan elites and the mass electorate. Partisan elites include presidents, members of Congress and state legislatures, and candidates for major political offices. A party's position and reputation on a political issue is established through the public acts and pronouncements of their elites. When a president sets out his position on an issue in the State of the Union Address or when senators express their opinions on an issue through their roll-call votes, they are helping to build the position of their party on a given issue. When this process is repeated over time and in different political arenas, the party establishes a reputation on the issue.

A party's reputation on the issue, in turn, serves as a partisan cue to the mass public.

But why do elites of different parties adopt contrasting positions on at least some political issues and how does this process begin? Riker (1982) suggests a plausible answer. A political party, finding itself temporarily in the minority, always has an incentive to defeat the majority winning party and, according to Riker, political issues are a natural vehicle for this purpose. New issues – if they can split the coalition of the majority party and are sufficiently attractive to the electorate – can turn old losers into new winners (and old winners into new losers) (Carmines, 1991). Thus, for Riker, losing minority parties always have an electoral incentive to adopt distinctive positions on new issues in their never-ending quest to upset the current status quo. And for the same reason, minority parties are particularly attentive to the appeals of grass roots political activists who are looking for parties to advance their political causes.

Riker's logic can also be applied to minority factions within majority party coalitions. For example, the new left operating within the majority Democratic coalition appealed to anti-Vietnam War forces and those on the left on the new moral and cultural issues of abortion and gay and women rights to help it take control of the party in 1972 (Layman, 2001). The point is that it makes sense for losing and disadvantaged political elites to develop and advertise new issue proposals in an effort to improve their public standing and gain political leverage.

The other major group in the issue evolution process is the mass electorate. The political masses are not only less active in the political process than elites they also have no particular incentive or capacity to create new issue alternatives themselves. Their key role in issue evolution is to respond – or, more frequently, fail to respond – to the issue cues of party elites. Moreover, even when the citizenry does respond to the issue cues of partisan elites, it does not do so instantaneously. Instead, the response is gradual, delayed, and protracted.

The Sequence of Issue Evolution

According to Carmines and Stimson's model of issue evolution, changes in elite partisan behavior do not lead directly to mass partisan response. Rather, two intervening steps are necessary to link elite policy shift to mass issue realignment. First, the mass electorate must perceive a difference in the issue positions of the parties. But awareness of party differences on an issue, by itself, is not likely to lead to mass issue realignment. Citizens must care about the issue. The changed perceptions of the parties on the issue must carry with them a strong dose of affection and disaffection for the parties if they are to overcome the stubborn inertia of existing partisan identifications (Campbell et al., 1960). Only when these two intervening conditions are met – clarified mass cognitive images of the parties and polarized affection toward them – will issue reorientation among partisan elites lead to changes in mass issue alignment.

Time ordering is critical. That is, the issue evolution process should follow a specific temporal sequence with changes in the cognitive and affective images of the parties occurring after elite reorientation on the issue but before mass partisan response. According to Carmines and Stimson's model of issue evolution, party activists play a pivotal role in this process, linking elite initiatives to mass responses.

Illustrations

What partisan changes have been illuminated by the issue evolution model? Let us consider three cases of issue/partisan change in contemporary US politics that have been examined through the lens of the of issue evolution perspective. For other examples, see Burns (1997) on taxes, Fordham (2007) on defense, and Shoch (2001) on trade.

Racial Issues

Carmines and Stimson (1989) offer a detailed account of racial politics in mid-twentieth century America as an example of issue evolution. Historically, Republicans – the party of Lincoln – had a more progressive racial tradition than did the Democrats with their support first of slavery and later of segregation. But during the mid-1960s their positions on race became reversed. The Democrats became the party of racial liberalism while the Republicans became the party of racial conservatism.

Carmines and Stimson show that this partisan transformation on race closely followed the model of issue evolution. In the first place, the change was gradual and incremental, unfolding gradually over many decades instead of within a single critical election. Indeed, according to evidence collected by Schickler (2013) the parties' altered positions on race have their origins in the late 1930s when a series of developments began to indicate that the Democratic Party rather than the Republican Party would eventually become more hospitable to blacks' civil rights. Through an analysis of

presidential speeches, party platforms, and congressional roll-call votes, Carmines and Stimson demonstrate that partisan elites altered their racial positions years before mass partisans reversed their positions. There was strong evidence, in other words, that elites rather than the general public initiated the issue evolution on race. Finally, the racial issue case follows the sequence of changes postulated in the issue evolution model. The process began with reorientation among partisan elites and ended with mass issue realignment but bracketed between the beginning and ending of this process was the electorate's increasingly accurate perceptions of the parties' racial positions and polarized affections based on them. Party activists played a crucial role in clarifying for the public the evolving racial positions of the parties through their highly visible activities undertaken during election campaigns. All in all, the partisan transformation of racial issues fits the issue evolution model extremely well.

Abortion

Changes in the abortion issue during the 1980s and 1990s provide another example of an issue that has undergone a partisan evolution, according to a study by Adams (1997). Examining roll-call votes in the House and Senate, Adams shows that Democrats and Republicans were only moderately divided over abortion throughout the 1970s. But, beginning in the early 1980s, the difference between these partisan elites grew steadily during the next 15 years. By the mid-1990s, congressional Democrats clearly had adopted the pro-choice position just as Republicans had become overwhelmingly pro-life. This change unfolded gradually and incrementally over a two-decade period, a pattern predicted by the issue evolution model.

Mass partisans have also become more polarized on abortion during this period, as Adams demonstrates through an analysis of public opinion polls. Throughout the 1970s, and up until the mid-1980s, Democrats, in the aggregate, were actually more pro-life than Republicans. But during the 1990s a partisan shift occurred, resulting in Democrats becoming significantly more pro-choice than Republicans.

Adams shows, finally, that there is likely a causal connection between the elite and mass changes, with elite-level changes producing mass level responses. Not only did the shifts in abortion attitudes occur earlier among partisan elites than among ordinary partisans but the degree of issue polarization is sharper and more pronounced in the former than the latter. Further, other research demonstrates that party activists played a key role in the partisan transformation of the abortion issue (Carmines and Woods, 2002).

In sum, in every major regard, abortion is consistent with the issue evolution model. Issue polarization gradually develops among both partisan elites and masses and as the issue cues of partisan elites become clearer and more distinct over time the partisan masses respond more readily to them. The process culminates in issue realignment among mass partisans.

The New Religious Divide and Moral and Cultural Issues

In *The Great Divide: Religious and Cultural Conflict in American Party Politics* (2001), Layman provides a comprehensive account of how the new traditionalist–modernist cleavage in American religion has come to shape the contemporary American political party system, the extent to which the religious and cultural divide between the Democratic and Republican parties has grown over time, and the process through which this growth has occurred. Similar to Carmines and Stimson's discussion of the types of issues capable of creating issue evolutions, Layman contends that the traditionalist–modernist religious cleavage came to affect party politics because it is associated with political issues that are easily understood, arouse strong emotions in a large number of people, reflect a deep-seated social conflict, cut across the lines of party conflict that existed in the 1970s, and appealed to the strategic incentives of certain groups of politicians within both parties.

He draws on the issue evolution framework to develop a model of the process through which polarized stands by party leaders on cultural and moral issues such as abortion, gay rights, and the role of women have been translated into changes in the religious composition of the parties' coalitions. Party activists have played a significant role in making this connection by sustaining and extending elite polarization and by providing cues to an inattentive public about the nature of issue change at the elite levels of party politics. The mass electorate gradually responded to elite- and activist-level change by first adjusting its perceptions of and affect toward the parties, and ultimately by reshaping its partisan ties along traditionalist–modernist religious lines.

Layman's research shows that the process of partisan religious change generally has followed the patterns predicted by the issue evolution model. It began among party elites and activists and activists also provided the link between elite-level issue change and the response by a relatively inattentive public. Over time, the mass public has come increasingly to see differences in the positions of the parties on cultural and moral issues and to care about these differences. These changes in mass perceptions of the parties and affect toward them have led ultimately to a substantial shift in the religious and cultural composition of the parties' electoral coalitions.

Issue Networks: Iron Triangles, Subgovernments, Policy Communities, Policy Networks

Mark Thatcher and Juergen Braunstein, London School of Economics, London, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

As policy making has increasingly been recognized to involve interest groups, analytical frameworks have been developed of state–interest group relations. Initially, there were limited and simple categories, such as issue networks, iron triangles, and policy communities. However, more complex policy network 'models' have been created that offer typologies of state–interest group relations and then seek to explain the forms of such relations. Most recently interorganizational approaches to policy networks have been established that draw on institutional and collective action frameworks that examine policy making by studying how the formation of ties among actors influences network output and the interaction among actors. Network frameworks allow inclusion of public and private actors and represent a move away from seeing policy making as an activity confined to public actors arranged in a simple hierarchy of relations.

Studies of issue networks and other forms of networks examine the relationships between interest groups and the state. As political scientists analyzed policy making, they found that simple models of representative government in which only elected officials and political parties took decisions and had a clear, coherent overview of policy across government were inadequate. Instead, interest groups were active participants in decision-making and implementation, building up close relationships with elected and unelected officials. Policy making was fragmented, with differing participants and relationships in each segmented policy field.

Early Development

Initially, in the 1960s and 1970s, there were two distinct views of the relationships between interest groups and officials. 'Iron triangles' and 'policy communities' suggested that very closed 'subgovernments' of stable participants in long-term relationships effectively made policy in well-delineated policy fields such as agriculture or defense. In the United States, 'iron triangles' were composed of the interest groups active in a particular policy field, members of Congress (especially those sitting in the relevant committees), and officials (particularly unelected) in the relevant parts of the bureaucracy with powers in the field. These actors knew each other, were in constant interaction and exchanged concessions, advantages, and information. They were a closed group, able to exclude outsiders. The concept of 'policy community' was used and developed in studies of Britain from the 1970s onward (Jordan, 1990). Policy formation was argued to be segmented into subsystems composed of policy communities of civil servants from government departments (or units within them) and interest groups. They were built on exchange relationships and a sense of 'community,' and possessed a set of dominant values (Richardson and Jordan, 1979). Both iron triangles and policy communities paid close attention to interest groups with powerful and continuing material interests, the basis of exchange relationships.

The concept of 'issue networks' was developed by Hugh Heclo in opposition to the 'iron triangles' literature in the United States, which he argued monopolized attention on closure and subgovernments, but ignored forces for fragmentation and the development of new forms of interest groups (Heclo, 1978). An issue network consists of a large number of issue-skilled 'policy activists' drawn from conventional interest groups and sections of the government, together with academia and certain professions but also comprising expert individuals regardless of formal training. Participants are constantly changing, and their degree of mutual commitment and interdependence varies, although any direct material interest is often secondary to emotional or intellectual commitment. No one is in control of the policies and issues covered by a network and it is very difficult to identify clearly the dominant actors.

Neither policy communities nor issue networks offered a free-standing, developed model of policy making (Thatcher, 1998). Rather, they represented enriching metaphors and useful concepts that were empirically applicable, and provided counterbalances to previous well-established views of policy making. They encouraged disaggregated analysis and drew attention to the effects of the fragmentation of government into subsystems, the interdependence of government and interest groups, and increased specialization in policy making. However, issue network, iron triangle, and policy community literature suffered from several limitations: they covered only specific categories of relations between groups and officials; they omitted key aspects of policy making, such as ideas, the distribution of power among actors, and change; the factors explaining the emergence of different types of an issue network or policy community remained general.

Network Typologies

In the face of these limitations, more general network approaches were developed. One path involved creating typologies of networks. The concept of 'policy network' or sometimes 'policy community' became generic, covering different forms of relationship between interest groups and officials arising from variations in networks characteristics. Rhodes and Marsh (1992) offer a six category typology

covering a continuum from issue networks to policy communities and based on differences in the degree of integration, membership, and distribution of resources among members. Jordan and Schubert (1992) claim that different terms for state/group relations in fact refer to variants of networks and hence they place terms such as iron triangles, clientelism, subgovernment, policy community, and various types of corporatism and pluralism in relation to each other using three 'dimensions,' namely number of members, whether the network is sectoral or transectoral, and the level of its stability.

In extending the scope of networks, the typologists pursue more ambitious theoretical aims. They seek to relate existing different terms and categories to each other within one overarching typology in order to avoid a jumble of overlapping and confusing terms. They claim to assist in ordering and categorizing information, permitting policy subsystems to be described, classified, and compared. Explanatory aims have ranged from specifying the key characteristics of policy networks in order to allow the systematic ordering of material, linking the 'structural' features of state and society and policy making (Atkinson and Coleman, 1989) and offering a 'model' of the role of interest group intermediation based on different forms of power dependence embodied in the types of network (Rhodes and Marsh, 1992).

Yet network typologies have suffered from considerable difficulties (Dowding, 1995). Terminological disputes over whether the generic term should be policy network or policy community have created confusion. Placing differing forms of state–interest group relations under the heading of 'policy network' has not led to a common terminological currency. As the concept of policy network/community became generic, definitions have become loose and frequently contradictory. The empirical applicability of network typologies has encountered important obstacles. Several of the 'dimensions' that form the basis of categories are difficult to operationalize, or are unlikely to generate agreement between different researchers; examples include the 'degree of integration,' 'preeminence,' 'serving the interests of producers' (Rhodes and Marsh, 1992). Categories are poorly defined and identifying a type of network in practice is difficult, since categories are not mutually exclusive and different types of policy network or aspects of several network types can exist in the same policy area.

Interorganizational Analyses

An alternative generalizing strategy has been to develop interorganizational analyses of networks. Drawing on social network analysis and work on interorganizational relations, they view policy making as an example of decision-making by interdependent actors who engage in exchange relations (Knoke et al., 1996). Policy is seen as the product of complex interactions among actors drawn from both 'public' and 'private' sectors. Such actors are partly interdependent but also partly autonomous. They are linked horizontally without being part of a single organizational hierarchy; their relations are based on exchange, thereby producing policy networks, but nevertheless combine elements of conflict with those of cooperation (Marin and Mayntz, 1991). Analysis focuses on the interaction of actors; the unit of analysis consists of the relations among network participants.

Interorganizational network analyses 'map' network structures, using qualitative and quantitative methods to reveal linkages between actors. Frequently mathematical techniques derived from formal network analysis are used to establish the network position of actors and relationships among them, applying indicators/measures such as intensity of communication, reputation among network participants, or resources. Mapping networks to provide a systematic picture of linkages serves several purposes. It draws attention to the interrelations and interdependence between public and private actors. Quantification enables complex patterns to be revealed that would be difficult to find because the events studied are too numerous, vast, and/or scattered and allows comparison of networks across sectors, countries, and time periods. The most important ambition of interorganizational approaches is to offer a 'structural analysis' by looking at patterns of network relations. It is insufficient merely to analyze the attributes of individual actors, for the influence of such attributes on behavior depends on the network of relations of each actor (Emirbayer and Goodin, 1994). Instead, relations among actors must be studied as a whole. A structural analysis of private and public actor configurations in policy formation identifies the position of actors and the ways in which networks influence actors' capacity to use their resources. It therefore permits explicit consideration of the ways in which different structures create different mechanisms or logics in policy making.

The scope of interorganizational approaches is very broad. Thus, for example, policy network refers to 'structures' located 'beyond or between policy markets and policy hierarchies' that are composed of 'relatively autonomous action units' (Marin and Mayntz, 1991). From an 'organizational state' perspective, Knoke et al. have conceived policy networks as relations linking organized interests with public officials, transforming heterogeneous communities of policy actors into webs of common benefit-seeking actors (Knoke et al., 1996). To operationalize and apply in empirical studies, important choices must be made to narrow down the scope of interorganizational networks. Similarly, applying quantitative techniques requires the choices over matters such as questions posed, categories created, the relationships to be analyzed, and variables to be controlled for. Social network analysis may embody a particular 'theoretical orientation' toward the structure of the social world, notably the need to study behavior as a set of relationships, but it provides a particular set of concepts and methods and a framework for testing arguments/models rather than a substantive set of hypotheses or a specific body of substantive theory. Social network analysis is good at explaining stability and continuity of networks and policy outcomes by drawing attention to networks as forms of interest intermediation or as new forms of governance, which substitute government. However, these approaches poorly explain changes in policy networks and changes in policy outcomes (for a summary of the argument see Richardson, 2000).

Analyzing Networks and Change

Addressing this criticism, more recent network research focuses on explaining changes in policy networks as well as changes in policy outcomes over time by adding additional explanatory

factors. These include ideas, processes and mechanisms, and contextual macrolevel factors (Daugbjerg, 1999; Peterson, 2003). Networks are perceived as intermediating and opportunity structures through which ideas, individual and group preferences operate to influence policy outcomes. As such these studies argue that the mere existence of ideas and preferences fails to explain or predict the specific design of policy. Therefore, they suggest looking at networks as intervening variables in order to understand national differences in the implementation of ideas into policies (Daugbjerg and Pederson, 2004). Furthermore they propose to integrate macrolevel factors such as the impact of national and supranational institutions with veto points at the mesolevel network dynamics.

Analyses outline the linkages between networks and policy outcomes, as well as the relationship between broader macrolevel institutions and subsystems, often by using case studies to illustrate connections. They identify differences in policy outcomes and relate them to variations in network structures in increasingly systematic cross-sectoral and cross-national comparisons (Howlett, 2002). In addition, research draws attention to the need to go beyond correlation toward more causal analyses. Studies increasingly try to outline a set of causal mechanisms connecting a set of explanatory variables to the explananda, which can either be policies or the network itself. They seek to identify the processes through which policies or networks came about and to reconstruct them through historical narratives. Thus far only few attempts have been made to integrate mechanisms from different disciplines, such as cognitive psychology (see Hindmoor, 2009), into social network analysis. Thus for instance, Hindmoor (2009) looks at how policy makers' preferences are formed in contexts of uncertainty. By drawing on cognitive psychology literature he identifies 'priming' (convincing people to believe something through releases, articles, interviews) as a mechanism of persuasion whereby social networks operate to influence policy decisions. Empirically, he uses the framework to examine how different policy network structures influenced different responses to foot and mouth disease.

Increasing the Theoretical Leverage of Social Network Analysis

Another stream of research aims to deepen the theoretical and explanatory leverage by linking up network frames with other analytical approaches (see Thatcher, 1998). It suggests that combining network analysis with other established analytical frames means complementing subsystem/mesolevel analysis, with insights from micro- and macrolevel analysis. Drawing on various forms of new institutional as well as rational choice and constructivist analyses social network research attempts to further develop and test hypotheses.

Recent positivistic accounts go beyond earlier interorganizational network analysis by linking statistical-descriptive and inferential analysis to theories of institutional analysis and development (see Lubell et al., 2012; Ward et al., 2011) and collective action (Sandström and Carlsson, 2008). Analyses linking up with collective action frameworks investigate how network structure relates to how actors are connected within a network and how this can influence policy. Social networks are perceived as opportunity structures, which can impose constraints on collective action. As such location and connection of actors within the network have important implications (for example, the size and diversity of a group influences collective action). Studies look at factors that influence the formation of linkages in networks and investigate the impact of networks ties on individual behavior and attitude.

They apply multivariate statistics to test hypotheses about the influence of networks on a variety of explananda, such as network performance. To capture interdependency effects among different actors within social networks research draws on different estimation techniques, including quadratic assignment procedure, exponential random graph models, and stochastic actor-oriented models (for an overview see Lubell et al., 2012; Ward et al., 2011). They utilize them in connection with longitudinal and cross-sectional data for analyzing different aspects of network formation. For example, stochastic models are frequently applied to longitudinal datasets for measuring interdependency effects and change over time (Snijders et al., 2010). Changes are analyzed with reference to earlier observations and studies investigate how individual actors shape social networks through the formation of ties among actors. While stochastic models assume that actors choose ties that maximize their utility, exponential random graph models are frequently combined with other theoretical frameworks. For example, Lee et al. (2012) draw on an institutional collective action framework (see Feiock and Scholz, 2010; Scharpf, 1997), which guides their expectations about the conditions under which actors are expected to cooperate and structures are expected to evolve. In contrast to stochastic models, exponential random graph models rely specifically on cross-sectional data, which offer a snapshot of a network at a particular moment in time. This has the advantage of capturing the whole network dynamics (e.g., network centrality) at a certain point and testing it against hypotheses. Together these inferential models can make predictions about tie formation among actors and the impact of these on other network performances and how network structures mediate actor relationships.

One critical aspect of positivistic analyses is their reliance on complete information. Because social networks are analyzed as structures, researchers need to have a totality of data, which reflects accurately the totality of connections among actors (Ward et al., 2011). Incomplete data affects the reliability of statistical measurement. To address the missing data researchers increasingly integrate so-called 'latent space approaches,' which are based on Bayesian data augmentation to account for unobserved data (Koskinen et al., 2010; Hoff et al., 2002). The calculated likelihood is related to observed patterns. As long as the missing data is random, the application of inferential statistics allows making accurate predictions. Consequently, unobserved systematic patterns have a critical impact on results. Despite recent advancements, even proponents of latent space approaches, most notably Lubell et al. (2012), acknowledge the need for further refinement, specifically with regard to large populations with unknown nodes.

Dialectical approaches were developed as a critique of positivistic social network analysis. In an attempt to go beyond

'simple causal models' and highlight the complexity of the relationship between network and agency Marsh and Smith denote the notion of a dialectical policy network analysis. They specify dialectical as the "interactive relationship between two variables in which each affects the other in a continuing iterative process" (Marsh and Smith, 2000: 5). This relationship refers to structure of network and agents, network and context, and network and policy outcome. Based on that they formulate a set of logic and broad statements – for instance, arguing that external factors as well as agents' decisions affect network formation, that policy outcomes are the results of interaction between agents and structure, that policy outcomes influence networks as well as being influenced by, and that network change is a product of the interaction between the context and the network. However, these statements are not specific enough to provide testable hypotheses and they are also not explicating mechanisms. Dialectical studies use qualitative methods, often focusing on sectoral comparisons within countries across time. Studies in this tradition share a critical realist ontology and maintain that policy making takes place in a multilayered self-organizing subsystem (Marsh and Smith, 2000; Evans, 2001; Toke and Marsh, 2003). Networks are in a constant mode of change because actors within the network interpret context and policy feeds back through network structures. To fully understand policy outcomes one needs to examine the interactive relationships. These models are complex and difficult to test because they attempt to explain the emergence as well as the change of networks as well as the content of policy outcomes.

Decentered analyses go further by adopting an interpretative perspective. By drawing on an antifoundational perspective (Bevir, 2003) decentered approaches apply a constructivist anthropological perspective, which emphasizes the importance of discourse, beliefs, tradition, and meanings (Bevir and Richards, 2009). Their primary focus is on network creation, by investigating how networks are created and altered through individual action. These actions are not conditioned by institutional norms but by beliefs, which individuals adopt against the background of traditions and in response to dilemmas. Decentered approaches maintain that in order to understand practices and institutions the researcher needs to understand meaning, beliefs, and preferences of peoples involved (Bevir and Rhodes, 2010; Bevir and Richards, 2009). Decentered approaches aim to investigate people's beliefs and practices by qualitative methods. They are using historical analysis to understand traditions and using ethnographic analysis and tools, such as studying individual behavior in context, unstructured approach, observations, textual analysis, oral histories, biographies, to investigate beliefs and practices. The ambition of decentered approaches is to "[turn] current approaches to networks on their head" (Bevir and Richards, 2009: 8)

Located between the extreme position of positivistic inferential and interpretative-decentered approaches, the advocacy coalition framework is an alternative partner for social network analysis (Thatcher, 1998). According to the advocacy coalition framework bounded rational actors are expected to rely on policy core beliefs and form coalitions with other actors to pursue common objectives. Policy outcomes and policy changes reflect belief systems of actors within subsystems. The unit of analysis is the subsystem, which can overlap with other subsystems and can be nested in other macro systems. Subsystems can be linked to policy change through policy learning (i.e., changes in beliefs), external subsystem events; internal events; cross-coalition learning. Advocacy coalition frames focusing on the role of ideas to explain policy outcomes and drawing on concept of advocacy coalitions. Based on their belief systems, actors can be aggregated into coalitions. Similar belief systems reduce coordination and transaction costs among actors.

Advocacy coalition frameworks apply quantitative and qualitative methods in order to explain internal logic of subsystems and policy change/content. Studies analyzing policy change and content apply qualitative methods to outline the mechanisms and processes whereby network characteristics affect policies (see Nohrstedt, 2011; Albright, 2011). They explain how and why advocacy coalitions affect policy changes through processes that link external events to coalition responses and policy outcomes (Albright, 2011; Nohrstedt, 2011). By drawing on cross-temporal comparisons, these studies refine existing advocacy coalition frames with regard to causal mechanisms.

Analyses investigating the internal logic of social networks and explaining advocacy coalitions are primarily quantitative (Matti and Sandström, 2011; Ingold, 2011). They focus on how individual beliefs shape policy networks and how external events are mediated through advocacy coalitions. Similar to other positivistic approaches, quantitative advocacy coalition analyses rely on statistical tools. They identify coalitions in policy areas by using block models (Imgold, 2011), and linking coordination and beliefs within policy areas by utilizing quadratic assignment procedure (Matti and Sandström, 2011). Responding to earlier criticism, most notably Schlager (1995), recent advocacy coalition accounts integrate aspects of collective action and testing whether similar beliefs lead to similar coordinated action (Weible and Sabatier, 2005).

Conclusion: Constant Expansion

Thus analyses of networks have become increasingly broad: from modest origins as concepts of issue networks and iron triangles, they have expanded to overarching frameworks of relations between public officials and private interests.

Differences in epistemological and ontological traditions among diverse theoretical lines of inquiry have regularly led to differences and sharp debates (see Marsh and Smith, 2000; Dowding, 1995, 2001). While there are those, most notably Marsh and Smith (2001) and Bevir and Richards (2009), who call for more constructivist perspectives in social network analysis by using anthropological and historical approaches, others, such as Dowding (1995, 2001) and van Bueren et al. (2003), suggest a positivistic empiricist approach by developing network analysis with rational choice approaches, such as game theory or actor-centered institutional analysis. Hence recent developments in network analysis offer a powerful example of the split between highly positivist analyses using quantitative and formal techniques, and interpretivist and constructivist studies that increasingly promote ethnographic studies.

Abstract

John Hughlings Jackson (1835–1911) was arguably the most influential thinker in the history of neurology. He elaborated the localisation of function in the human brain on the basis of clinical observations in patients with brain lesions and epileptic seizures. His work induced the first experimental studies that further established the structure–function relationships in the brain. He also laid the ground for our understanding of the nature of epileptic discharges.

John Hughlings Jackson was born in Providence Green, Yorkshire, England on 4 April in 1835, of English antecedants on his father's side and Welsh on his mother's (Critchley and Critchley, 1998). His father was a gentleman farmer and a brewer who, as a surviving letter shows, was a wise and kindly man. Jackson's mother died aged 29 when he was one year old. He was educated at an undistinguished boarding school which he left at the age of 15, and did not go to university. In later years 'he held that by exemption from over-teaching his mind had retained more of freedom and energy than might otherwise have been the case' (Hutchinson, 1925).

When Jackson left school he was at once apprenticed to a general practitioner in York. Two years later, in 1852, he enrolled at the York Medical School and in 1855 he proceeded to St. Bartholomew's Hospital in London. He qualified in 1856 and returned to the York Dispensary for three years as a resident medical officer. In 1860 he submitted a thesis (the title of which is unrecorded) to the University of St. Andrews and was awarded the MD.

By this time Jackson had returned to London. He had become increasingly interested in philosophy and seriously considered abandoning medicine for this field. He was dissuaded by his friend Jonathan Hutchinson (who later became one of the leading surgeons and ophthalmologists of his day). About this time (Hutchinson records) Jackson came under the influence of C E Brown-Sequard who 'told him strongly, that it was foolish to waste his efforts in wide observation of disease in general, and that if he wished to attain anything he must keep to the nervous system' (Hutchinson, 1925). As a result, Jackson was appointed in 1862 to the staff of Brown-Sequard's hospital, the National Hospital for the Paralysed and Epileptic in Queen Square. In the same year he became a clinical assistant at the Royal London Ophthalmic Hospital (now known as the Morefields Eye Hospital) in London and in the following year he was appointed to the London Hospital. These three institutions provided him with the experience on the basis of which he made his fundamental contributions to our understanding of the organization of nervous function.

Jackson was a shy, modest, self-effacing individual, much loved by his students and colleagues. His wife died after only eleven years of marriage. A place at the lunch table was always set for him at the home of his colleague Dr. Thomas Buzzard. Jackson came to lunch irregularly and without notice. As Buzzard's son recalled, '... he would pull a chair up to the table, exchange a few remarks, perhaps tell a humorous story with only a twinkle of the eye disturbing the solemnity of his features, and after five, perhaps ten minutes he would mumble something about remembering an engagement and leave the room' (Buzzard, 1934). In his last years Jackson lived an even more solitary, though serene life. He retained an interest in the lives of his pupils and their families to the end. He died on the 7 October 1911. His contribution was widely acknowledged by the academic world during his lifetime, but to the surprise of all he received no national honor.

Jackson's contemporaries and pupils recorded that he was a meticulous observer of clinical phenomena, and from his earliest days in medicine he was committed to the necessity for pathological verification of clinical inferences. His understanding of the nervous system based on this approach was molded by two main influences. The first derived from his teacher at medical school, Dr. Thomas Laycock (later Professor of Medicine in Edinburgh) who was interested in psychology and in nervous function and dysfunction. The other influence was the writings of the philosopher Herbert Spencer with whom Jackson corresponded up to the beginning of the twentieth century. It was from Spencer that Jackson derived the notion of the evolution of nervous function, which led to his idea of a hierarchical arrangement of functions, and that disease (neurological and psychiatric) led to a successive regression from the 'least automatic' and 'least deeply organised' to the 'most automatic' and 'most deeply organised' levels. As Walshe (1961) has pointed out, these ideas derived from Jackson's lifelong study of five kinds of clinical phenomena: focal seizures, chorea, hemiplegia, speech disorders, and mental disorders.

A remarkable consequence of Jackson's work was his prediction, on the basis of unaided clinical observation, of

[†]Deceased.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61058-9

a number of physiological principles which were later confirmed experimentally. One of them is the concept of localized cerebral discharges generating focal seizures, and that such focal seizures are caused by local brain disease. The comparison between the clinical symptomatology and subsequent neuropathology showed that the distribution of focal motor and sensory signs depended on the site of the lesion. The topographical structure–function relationships laid the ground for the topological functional organization of the cortex long before cytoarchitectonic anatomical maps were established. The general idea of the functional specialization of the cortex had already been proposed by Gall (1825). His phrenology was derived from the attribution of certain personality features to the individual 'microstructure' of the scalp as inferred from palpation. Gall's postulate that cerebral function must be localized was correct in principle but based on inadequate evidence. The first real evidence came from Jackson, who published his first account of epilepsy in 1861, almost 10 years before his clinically based concept was confirmed by using electrical stimulation of the cortex (Fritsch and Hitzig, 1870; Ferrier, 1876).

The first pioneers of cortical neurophysiology indeed recognized the pivotal role of Jackson in the development of the concept of epileptogenic discharges in distinct areas generating focal seizures as the following two quotations show: '... I was precisely the first one, now some thirty or more years ago, to confirm by *physiological experiment* and to define more closely that which Hughlings Jackson had concluded from clinical facts' (Hitzig, 1900); '... Dr. Hughlings Jackson who from a clinical and pathological standpoint anticipated many of the more important results of recent experimental investigation into the functions of the cerebral hemispheres. (Ferrier, 1886).

Another concept put forward by Jackson related to the effect of lesions on function. In order to understand the pathophysiology of the effects of lesions he introduced the term 'negative and positive elements.' The negative elements were derived from the more global effects of epileptic seizures as apparent from dreamy states and the loss of consciousness. This was regarded as a dissolution 'of so many nervous elements of the highest centres' by the epileptic discharge, so that the 'most special and complex sensorimotor arrangements' would affect the adjustment of the organism as a whole to the environment. Convulsions were recognized as due to excessive neuronal discharge. From his clinical observations Jackson deduced that 'there are two ways in which nerve tissue suffers. It may be destroyed, and then there is loss of function. It may be unstable, and then there is disorder of function – discharge' (Jackson, 1931, vol. 1, p. 29).

The 'positive element' was exemplified by speech disturbances, where the inability to express oneself demonstrates the negative effect of a brain lesion, whereas the paraphasia – the insertion of wrong words or inadequate sentence formations – would show the effect of the damaged part on the function of the remaining neural circuitry. These views later inspired Sigmund Freud's contributions to aphasia, in particular his early insight into the emotional determinants of speech disruptions. The positive and negative elements also had an impact on subsequent hypotheses on psychotic disorders.

Jackson's explanation of the clinical deficits associated with lesions was based on his view of the three levels in the evolution of the nervous system. Each element of each level was seen to contain a complete representation of the next lower level. Consequently, each element of the middle and highest levels would contain a representation of the entire body. If the nervous system is damaged the clinical impairment is not due just to the damaged part, but represents the compensatory action of the lower level circuitry that would then partially compensate for the function of the destroyed tissue.

The concept of evolution of the nervous system was therefore instrumental to his view that dissolution of the nervous system due to the effects of lesions results from the function of the remaining, nondamaged parts being liberated from control by the damaged part. This approach to understanding the pathophysiology and nature of the neurological signs and symptoms was later replaced by 'localizationists' who considered these to be deficits in a mechanical framework, i.e., saw them as loss of function of the destroyed tissue. It soon became clear that phenomena like spasticity, tremor etc., could not be explained in this way. With the advent of new, experimentally-based conceptions of the brain as a complex, densely interconnected and reentrant network, the Jacksonian views were basically confirmed.

Jackson's contribution was not limited to the conceptual advances we have described. His skill in precise clinical observation, together with his analytical and deductive powers, led to advances of practical value in clinical neurology. For example, he was one of those who pioneered the introduction of the Helmholtz ophthalmoscope to medicine, his first paper on the topic appearing in 1863. His papers of 1871 and 1873 on 'optic neuritis' from intracranial disease, and the diagnosis of brain tumours, represented a major advance. He made contributions to neuro-ophthalmology, particularly in relation to eye movement, and to the effects of syphilis on the nervous system.

The writings of Jackson have a reputation for being difficult to read, being filled as they are with qualifications in the text and in extensive footnotes, as he strove to get as close as possible to the truth about inherently complex problems; they are still illuminating. Many appeared in *Brain* (of which he was a co-founder) but many others appeared in journals which are now difficult to obtain. Fortunately a comprehensive selection was published in 1931 and reprinted in 1958.

Abstract

Jane Jacobs' work has been influential in a broad and disparate range of disciplines including economics, sociology, psychiatry, journalism, playwriting, social activism, politics, urban planning, biology, and architecture. She is primarily remembered as a public intellectual, an activist, a champion of all things urban, and an irascible opponent of urban renewal models. She offered a particular diagnosis of what was wrong with the modern city, and a blueprint for urban recovery. While she has been criticized for her somewhat utopian portraiture of how city life might be, many of her practical recommendations for reimagining city space are integral to urban policy and planning practice today.

Introduction

Jane Jacobs' extraordinary intellectual legacy has lead to her being variously described as a visionary, urban philosopher, urban sociologist, urban economist, and urban designer (Hirt and Zahm, 2012). Her work has been influential in a broad and disparate range of disciplines including economics, sociology, psychiatry, journalism, playwriting, social activism, politics, urban planning, biology, and architecture. She is primarily remembered as a public intellectual, an activist, a champion of all things urban, and an irascible opponent of urban renewal models. She offered a particular diagnosis of what was wrong with cities, and a blueprint for their recovery. Many of her urban 'tactics' are an accepted part of urban policy and planning practice today. In sum, Jacobs was "an astute chronicler of urban life, she squarely addressed issues, eloquently showcased what worked, and advanced proposals for improving our cities" (Ellin, 2010: p. 45).

An autodidact, Jane Jacobs' incisive exploration of the modern urban form was largely based on her own self-directed research and learning. Her *modus operandi* might be termed serendipitous exploration. In correspondence with Richard Carroll Keeley in the late 1980s, she wrote about her approach to her work: "I read as omnivorously as I can manage, in anything that interests me. Seek patterns, explore them and look out for contradictions … messy, muddly, work which I am inclined to think that thinking maybe usually is" (Keeley, 1989a: p. 35). Jacobs practised the discipline of dialectical thinking and questioning, but her frame of reference was never abstract or abstruse. Rather, her life's work as a student of the city was grounded in the materiality of everyday urban life. She had a unique ability "to move from the particularities of the local interaction of incident and morphology to the larger patterns of urban life" (Sorokin, 2010: p. xvi). Inevitably, her excoriation of twentieth-century urban planning particularly in North America but also beyond, drew criticism from establishment figures within academe and architectural practice. Jacobs was dismissed as lacking both systematic disciplinary training and a grounding in theoretical knowledge. In fact, Jacobs' approach to her metier was to marry rigor and intuition, cool observation and empathy, historicity and an abiding and unerring sense of the human subject.

Biographical Facts

Jane Jacobs was born in 1916 in Scranton, Pennsylvania, and died in Toronto in 2006. Her father was a physician and her mother a former school teacher and nurse. She was raised a Presbyterian. After completing High School where she was a self-confessed 'trouble-maker,' Jacobs worked for a short time in her home city before moving with her sister to New York. Here Jacobs worked in a variety of secretarial and writing jobs which afforded her the opportunity to savor the geographical and sociological variety of the city. These experiences, she claims, "… gave me more of a notion of what was going on in the city and what business was like, what work was like" (www.pps.org/reference/jjacobs-2). She met a young architect Robert Jacobs during this period and he became her husband and lifelong comrade in arms. He died in 1996.

Jacobs began to develop a critical perspective on city planning and urban renewal during her period of tenure as associate editor of *Architectural Forum*, where she worked throughout the 1950s. After hearing her speak publicly about the threats posed by current urban planning policies to urban living, the distinguished urbanist and author William H. Whyte invited her to write an article in *Fortune* magazine, titled 'Downtown is for People.' On foot of this article Jacobs won a Rockefeller foundation grant to embark on her first and most well-known book, *The Death and Life of Great American Cities* (1961), "a prophetic text" (Suarez, 2010: p. 19) which would change her life, and influence generations of urban theorists and urban practitioners.

In the 1960s Jacobs took a very public role in opposing the urban renewal policies in New York City, favored by the city's Parks Commissioner Robert Moses. Her contribution to campaigns to stop building highways through historical neighborhoods and urban villages contributed to the defeat of the Lower Manhattan Expressway plan and the eventual fall from power of Moses. Furthermore, "Jacobs' harsh criticism of 'slum-clearing' and high-rise housing projects was also instrumental in discrediting these once universally supported planning practices" (www.pps.org/reference/jjacobs-2).

The Jacobs family left New York City in 1968 because of their opposition to the Vietnam War. Jacobs found the culture of Toronto very different to that of New York City. She believed that immigrants had more capacity to do things in the city than

she had observed in her native New York. She recalled that in the late 1960s there was little evidence that city precincts had been subjected to redlining (as had been the case in New York) and that ethnic populations were not ghettoized. Nevertheless in her adopted home she remained a critic of top–down city planning, and blockbuster developments which threatened the integrity of the city's neighborhoods.

Contemporaries recall that while she was best known in New York City for the struggles which she fronted in the 1960s, for Torontonians she became a significant and accessible mentor for those concerned about the development of the city (Greenberg, 2010). She took Canadian citizenship in 1974 and lived in Toronto until her death. Her qualities as an activist were legend. The New York Times obituary on her death referred to the 'steeliness beneath her folksiness' and quoted the Canadian weekly magazine, MacLean's which had feted her as 'a lioness in winter' (*The New York Times*, 26 April 2006). Jacobs remained a social thinker and activist with her feet very firmly planted on the ground. As Greenberg has observed "she refused to be deified or reified: she never wanted to be a guru and strenuously resisted the temptation to freeze her thinking into cult or dogma … and resolutely rejected being franchised" (2010: p. 117). Nonetheless, streets, walks, awards, medals, and fellowships are named after her.

Description of the Major Works and Publications

Jane Jacobs brought depth and complexity to how we view the city. She explored the city as a distinctive social space and economic space, and tracked the myriad ways in which the built environment, economic relations, and social viability of the city are interpolated. Hers is a powerful articulation of the interactive order of everyday city life that is frequently eclipsed by the focus on the competitive entrepreneurial city and the proliferation of civic boosterism. Moreover, Jacobs was an early critic of low-density, single use settlement patterns that have a deleterious impact on the environment (Kidder, 2012). Her approach followed the template of grounded theory, using empirical observation in the real world to generate sensitizing concepts that could be deployed as starting points for new research (Glaser and Strauss, 1967). Jacobs opposed abstraction and wrote in an accessible style. Her virtuosity resided in her ability to marry historical and comparative perspectives with case study analysis and personal observation.

Jacobs's first and most feted book *The Death and Life of Great American Cities* (1961) made an enormous impact on its publication which resonates to the present day. This work is the basis of her core reputation as a defender of cities, and of city streets. Indeed, it has been described as "a long paean to the humanizing, secure, child-friendly, and economically coherent nature of the urban street" (Suarez, 2010: p. 16). The book literally shook the planning and architectural establishment to its core, and it remains prescribed reading for each new generation of architecture, planning, and social science students.

For Jacobs, cities are an ongoing work accomplished by those who live, work, and socialize in them. Diversity, intensity, and creativity are the sources of their economic potential. In the tradition of the Chicago School and the ecological explorations pioneered by Robert Park in the 1920s, Jacobs approached the city as a laboratory of organized complexity to be explored literally from the ground up. She utilized a social processes framework by paying attention simultaneously to the economic, social, cultural, political, and regulatory forces that constitute the urban.

In *The Death and Life of Great American Cities* Jacobs advanced the view that a gradualist, evolutionary approach to urban development was preferable in terms of maintaining urban vitality to an intensive, deterministic approach then favored by urban planners. Jacobs vigorously opposed 'one size fits all' planning approaches. Rather she emphasized the benefit of "allowing places to evolve gradually through natural selection and infill development, with minimal government intervention and in careful consultation with local residents" (King, 2013: p. 2408). This view of the city as the outcome of ecological forces has been heavily critiqued from a political economy perspective, and from a planning perspective can be read as almost heretical. Urban planning in Western cities today proceeds through large-scale, public–private redevelopments, neighborhood-level regeneration programmes, and cultural projects designed primarily with the interests of capital accumulation in mind. They seek to appeal not to the local citizenry but to prospective gentrifiers and tourists. Yet, it is arguable that in two respects Jacobs' creed has been incorporated into planning practice: there is nowadays a greater respect for the urban vernacular and an acknowledgment that planners should take account of the lived experience of urbanites in planning and urban design.

The Death and Life of Great American Cities focused on four key dimensions of urban life which are summarized here: (1) The city is the natural progenitor of interactive human life. The nature of cities is explored by examining its public realm, sidewalks, parks, and neighborhoods, all of which Jacobs viewed as crucial sites of civic interface. Among her key theses that remains highly pertinent is the notion that collective security can be maintained through having low-level collective surveillance (eyes on the street) in vibrant public spaces. (2) The well-being and liveability of a city are connected to level of diversity. Jacobs understood diversity not so much in relation to population make up, but more in terms of different kinds of economic functions, the mixing of diverse cultural groupings and tolerance of diverse cultural practices. This is a perennial argument made about cities and has been repopularized in more recent times by writers such as Ray Oldenburg and Richard Florida. Her recipe for diversity included multifunctionality districts or neighborhoods, shorter city blocks that are more people friendly, architectural mingling of old and new, and greater density of urban populations. Diversity, Jacobs believed, affords opportunity for encounters with difference and with strangeness, and such encounters incite question, wonder, and discovery (Keeley, 1989b). Multifunctionality in neighborhoods creates the basis for diversity in urban life. (3) Cities are involved in processes of creative destruction through the forces of decline and regeneration, or what she termed 'slumming and unslumming.' She presciently argued that too much homogeneity or – as she termed it duplication of function – militates against diversity. Homogenization results in a loss of appeal, which in turn contributes to a spiral of decline resulting in urban stagnation

and decay. Interestingly, Jacobs references The City area of Central London as an example of dediversification, and predicted (rather accurately as it turns out) that eventually the City area and the adjacent West End "will become one dreary sea of office blocks" (1992: p. 149). (4) The final section of the book deals with tactics for restoring cities. Most of these tactics are now commonly deployed in urban planning and project development but they were highly innovative in the early 1960s. These include providing integrated social housing, limiting car usage in the city, revisualizing the city and city space through the application of design principles, opening up and preserving the public realm, and refashioning city governance.

The book is replete with examples and instances of the 'common good' which Jacobs sees in the lively neighborhood which acts as both a focus for place attachment and a space for civil interactions where people of the neighborhood, and those visiting or passing through can easily comingle. Jacobs believed that in cities that lacked a natural and casual public life, people would become socially isolated, they would "lack public acquaintanceship … and no practice or ease in applying the most ordinary techniques of city public life at lowly levels" (1992: p. 65). She contended that the public realm of the city must be open, accessible, and traversed by all. She recognized the significant role played by public characters, people who act as lynchpins within informal community networks, ensuring the transmission of information within those networks. Jacobs went on to identify another important constituency – the hop-skip people – whose role is to make links across neighborhoods, creating a summative district neighborhood. Though she does not use the terminology, Jacobs inadvertently subscribed to the now commonplace view that loose ties with others can forge bridging social capital, which complements the denser forms of social capital associated with communities where networks are intimately enmeshed. Hop-skip people are the civic minded, who move across and between networks and are the facilitators of genuine self-governance (Byrne, 1989). Such self-governance in the cause of achieving the common good can only emerge if there is sufficient economic prosperity in the city and the complexion is sufficiently diverse. In the book she paints an imagined urban community (utopia) constituted through diversity and dynamic interdependence. Moreover, she makes a key distinction between the goals of efficiency and creativity in the urban context. According to Jacobs, the two are not mutually exclusive but complementary: giving full rein to creativity heightens efficiency in the long run (Cichello, 1989).

Jacobs' work, though highly original, has many antecedents from within the social sciences. There is a clear debt to the Chicago School and their ethnographic observations of everyday life in the city. Her work also grappled with the modernist conundrum presented by the city, a theme that featured heavily in Georg Simmel's oeuvre. The latter was struck by the creative imperatives borne of the intensity, diversity and tempo of city living, and the struggle to retain subjectivity in the modern metropolis.

Like many classics, *The Death and Life of Great American Cities* generated controversy when first published but over time this has given way to an acknowledgment of the timeless insights which it contains. In the twenty-first century many of Jacobs's observations and prescriptions have become integral to how cities see themselves, and seek to be seen by others. Jacobs argued that grand planning schemes intending to redevelop large swaths of a city according to a central theoretical framework fail because planners do not understand that healthy cities are organic, spontaneous, messy, complex systems that result from evolutionary processes. The less master planning to which a city is subject, the more potential for an organic outcome, she believed. As King observes her framework of analysis suggests that neighborhoods that have experienced gradual rather than intensive redevelopment would experience better allocation of land uses, perhaps resulting in more walking, less vacant area, and a greater diversity of uses (King, 2013: p. 2409). Cities concerned with liveability nowadays are turning increasingly toward Jacobian principles focusing on creating more walkways and cycle paths through city streets, reducing the impacts of car culture, promoting 'living over the shop' schemes, developing the public realm of city centers and renewing high streets.

After the resounding success of *The Death and Life of Great American Cities*, Jane Jacobs took a more philosophical turn broadening her agenda to include discussions of the city in its economic context, and to explore the moral basis of social and economic relations. Subsequent books include *The Economy of Cities* (1970); *The Question of Separatism* (1980), an analysis of the case for Quebec sovereignty; *Cities and the Wealth of Nations* (1984), a prescient study of the urban city region as a counterpoint to the nation-state; *Systems of Survival* (1993), an exploration of the morality of commerce and politics; *The Nature of Economies* (2000), which employs an ecological frame of analysis to interpret the economic system, and *Dark Age Ahead* (2004), a work which explored how suburban sprawl might be tackled through more creative and intensive usage of land. Once again, Jacobs proved to be ahead of the curve given her concerns with making suburbia more sustainable. She extended her urban brief to the suburbs envisioning roadways being converted into urban streets and arterial routes transformed into boulevards that offered equal access to transit and cycle lanes. However, she suggested that such changes would only be possible on foot of a catalystic event such as an economic crisis (Greenberg, 2010). It is arguable that in Western cities at least, the effects of climate change coupled with economic crisis are leading toward a more pronounced focus on creating more sustainable cities and suburbs.

Jacobs' later works represented a sustained attempt to understand cities within the broader context of the political economy of the region and the state. With considerable forethought she anticipated the potential of cities as economic engines or incubators. In *The Economy of Cities* she analyses how cities come into being, and what they must do economically to flourish. The city she observes is "a settlement that consistently generates its own economic growth from its own local economy" (Jacobs, 1970: p. 258). Growth is envisioned in terms of human innovation and creativity through a process of discovery of new forms of work, through application of new knowledge, or recombinations of knowledge. The rise of the now ubiquitous creative quarters, digital hubs, and silicon alleys all bear powerful witness to her central thesis. Nevertheless, these economic growth engines remain niche rather than mainstream, and cities – even in the most advanced

societies – also continue to house sweet shops, to sustain informal economies, and to generate minimum wage service jobs.

Cities, Jacobs argued, operate through a reciprocating economic system which serves to catalyze relationships between cities. [In fact cities more often compete with each other for inward investment on an increasingly globalized stage.] Jacobs advocated a system of import substitution in cities as well as export development. From her perspective, export generation is the process by which cities increase the amount and range of goods and services that they trade (Cichello, 1989). This she believed would create a virtuous cycle or multiplier effect. Import replacement, on the other hand, can occur when the dynamic growth and innovation in the city make it possible to start producing locally what previously had to be imported. Once again, processes are central to her mode of analysis. The creatively minded entrepreneur is the instigator of this virtuous economic cycle, which she contended could create a sustainable growth model. From today's standpoint this reads as a particularly naive and nostalgic version of benign capitalism, a capitalism that could be locally tamed. But even as she was writing at the end of the 1960s, this version of capitalism was on the way out, and a far more rapacious form of neo-liberal capitalism was being ushered in.

The Economy of Cities explores the economic implications as opposed to the social implications of her liberal democratic model of the city (Kidder, 2012). She emphasized freedom and autonomy in relation to the economic activity of cities. Here she anticipated the growing strength of the urban regime, which to some degree challenges the nation-state nowadays as a site of economic activity through its own civic boosterism. She anticipated the emergence of the city and city regions as constituting new sites of power and political practice at subnational level.

A moral distinction is made in *The Economy of Cities* between commercial values (dominated by relations of commercial exchange) on the one hand and guardian values (adherence to a collective responsibility and orientation toward a shared common good) on the other. Her innate feel for sociology is evidenced here in her Weberian juxtapositioning of an ethic of rationality oriented toward means and growing out of a calculative frame of mind, with an ethic of ends which is much more concerned with the value systems that underpin our actions and engagements with others.

Cities and the Wealth of Nations (1984) has been described as her most ambitious project but also most pessimistic book (Keeley, 1989b). In this book, Jacobs built upon the microeconomic base elaborated in her earlier works, to develop a macroeconomic analysis that frames a theory of wealth, trade, growth, and decline of cities both individually and collectively (Cichello, 1989). She critiqued macroeconomic theory taking issue with the many anomalies that are thrown up by conventional economic theory predicated on a very narrow conceptualization of human behavior. (Once again, her critique was prescient. More than 50 years later the rise of behavioral economics points to a central concern of her life's work, namely, that context heavily affects the way we make decisions and take action.) The book which provides a critical analysis of economic development theory and offers a populist reading of global political economy develops further themes implicit in *The Economy of Cities*. The city is placed in the context of its city region or hinterland. Jacobs traced the stultifying effect on the economy of the displacement of the innovator by the bureaucratic corporation. Against this backdrop, she assessed the viability of the city-state. According to Jacobs, tradition has bound us to a system of nation-states, and the primacy of this economic unit has systematically blocked the innovative and dynamic potential of subnational economic units, cities. In this she anticipates the rise of the modern city-state which directly competes with nation-states for investment (see, e.g., the rise of metropolitan corridors such as the Rhine–Rhur metropolitan region and silicon valley in California). It is a fact today that a rising share of the economic action is urban. Even in the technology sectors, themselves traditionally suburban, capital is following talent to the city (Luce, 2014).

Jacobs as ever was interested in the lived experiences of urban resilience, local generation of wealth, microfinancing, and entrepreneurial development, particularly in the global South. Her writings take on an inevitable sepia hue when viewed from the purview of a digitally driven, hyper globalized world. Still, Jacobs did not shy away from confronting the failures of the economic system of national states, in the process challenging the foundations and premises upon which that system is predicated (Cichello, 1989).

Assessment

Jacobs' work lends itself to reading and rereading. Many of her predictions have been borne out and her analysis remains *au courant* for students of the city, and for those who seek urban transformation. Her ideas remain perennially popular. For instance, her contention that a mix of housing types to include older as well as newer buildings has a positive impact on social relations and the climate of sociability in a neighborhood continues to garner attention. A recent study tested Jacobs' hypothesis that mixed age buildings could foment enhanced social relations. Drawing on data in Chicago on housing stock age and data on rates of social cohesion, control, intergenerational closure, and reciprocal exchange King demonstrated significant links between housing age diversity (historical development pace) and measures of neighborly social relations, even when controlling for other neighborhood housing features, such as social composition and individual socio demographics (King, 2013: p. 2421). Although one cannot infer causality where a correlation holds, King suggests that these cross-sectional results do suggest the validity of Jacobs's argument.

In terms of her impact outside of the academy, her ideas have been taken up both by New Urbanism and Integral Urbanism movements. Integral Urbanism is a movement within urban design that aims "to heal the wounds of the modern and postmodern era by engaging in a range of restorative efforts incorporating five qualities: hybridity, connectivity, porosity, authenticity and vulnerability" (Ellin, 2010: p. 48). At its core this reorientation in urban design places value on process as well as product, something which Jacobs championed throughout her writing and activist career. Jacobs' influence on design thinking is detectable in the preoccupations with sustainable urbanism and the focus on place-making

among academics, policy-makers, and politicians today. Jacobs spent a lifetime defending public space against privatization, both in her scholarly works and in her political activism. Community participation in planning, community gain clauses in development plans, environmental assessment all exist today but are traceable directly or indirectly to the incisive and forensic account of a defective planning system promulgated in *The Death and Life of Great American Cities*.

There is a strong ethical dimension to her work, and particularly so in *The Death and Life of Great American Cities*, *The Economy of Cities*, and *Cities and Wealth of Nations*, which provided powerful arguments about the ethical underpinnings of liberal democracy (Kidder, 2012). She consistently endorsed the twin principles of individual and collective determination in cities. In this her work harks back to that of Simmel who saw cities as both arenas for intense social interaction and for the elaboration of subjectivity in the face of the encroachment of objective culture. Jacobs was concerned with freedom, autonomy, and diversity in the city all of which Simmel had seen as constitutive of the modern metropolis. In her life and her work she sought a balance between the expression of individual freedom and the ordered, rationalized world of the money economy where all is reduced to the question of 'how much?' Such questions intrigued Jane Jacobs and continue to exercise social scientists, architects, planners, and economists today. How do we achieve an equitable balance between "the freedom of the individual and the order of collective responsibility, between large scale organizations and small ones, between public life (we) and private life (I)" (Hamdi, 2010: p. 37).

Her belief that diversity and sociability are essential requirements of cities is reflected directly or indirectly in the work of many contemporary urbanists: the 'strength of weak ties' (Granovetter, 1973); the concept of the 'third place' (Oldenburg, 1989); the creative class thesis (Florida, 2002); the concept of 'civil integration' (Vertovec, 2007); the notion that 'civicism' is the key to identity in the modern world (Bell and de-Shalit, 2011); and the idea that cooperative relations are central to human success (Sennett, 2012), to name just some.

Critics have described her work as representing a Kuhnian paradigm shift in how we think about and theorize cities (Cichello, 1989). In particular, *The Death and Life of Great American Cities* published more than 50 years ago, emphatically threw down the gauntlet to planners, architects, and urban theorists wedded to modernism and urban renewal. Jacobs attempted to reframe the way in which the city should be understood (Keeley, 1989b). As Sorokin astutely observes she had a unique "way of looking that saw urbanity not in the reduction of its order to the regularity of clockwork but in its vivid spontaneity and expansive, ever-transforming difference" (2010: p. xv). Much as John Berger's, *Ways of Seeing* (1972) challenged the hegemony of Western cultural aesthetics by revealing the hidden ideologies of visual images, Jacobs' work challenged the taken-for-granted assumptions about city growth and urban dynamics, revealing the latent properties that make cities lovable and livable. She offered a powerful and compelling critique of the high modernist notion of the city as a machine for living promulgated by Le Corbusier. By contrast, for Jacobs "the living city can achieve a level of complexity, and promote an array of individual ends, that far surpasses any designed construction, whether physical or social, precisely because cities are the emergent, collective expression of many individual minds interacting day after day" (Ikeda, 2010: p. 27). The city for her is fundamentally a set of social processes, which themselves are always in a state of flux.

Jacobs has been criticized for the utopianism latent in her own vision of the city. In particular, her work veers toward an excessively nostalgic vision of diverse and intimate neighborhoods peopled by self-employed artisans, petit bourgeoisie, and urban entrepreneurs. Her vision of communal diversity animated at local level through ongoing interactions between neighbors involved in low-level surveillance of their mutually shared space, can if brought to its logical conclusion lead to a more dystopian version of urban reality-gated communities such as exclusionary communitarian movements which serve to socially polarize the contemporary city (Harvey, 2000). Moreover, Jacobs displays no real interest in, and presents no sustained analysis of issues of power, of class, of gender, of racial and ethnic cleavages all of which are germane to the constitution of city and urban conflict.

Jacobs' contribution lies in her capacity to cut through quantitative metrics and take into account the whole complex range of variables and processes that made up the city and everyday city life. This was no less than a call for a humanistic–interpretive approach to urban analysis as a substitute for the more positivist approach that dominated in the twentieth century, and in particular in the years after World War II. Hers was a clarion cry to the American public and to publics everywhere, an encouragement to citizens to think about processes; to work inductively rather than deductively and to seek the particulars (fragmentary evidence) which can provide more insight into the generalities (statistics and metadata sets) of how things operate (Jacobs, 1992[1961]: p. 440). She proved to be a formidable leader in charting this course, in the process creating a legacy that persists to the present day.

Abstract

Roman Jakobson was one of the major linguists, literary theorists, and semioticians of the twentieth century, and one of its most creative minds. He contributed to linguistics major fundamental concepts and showed the importance for linguistics of such diverse issues as child language acquisition, poetry, the act of communication, and typology and universals. After a brief overview of Jakobson's life, major themes of his work are discussed in detail: structural phonology, child language acquisition, and aphasia; distinctive features and functional view of sound; invariance and relational structure; functions of language; metaphor/metonymy (similarity/contiguity); grammar; and Jakobson's legacy in linguistics and other fields.

Roman Jakobson (1896–1982) was one of the major linguists, poeticians, and semioticians of the twentieth century. He contributed to linguistics such concepts as (distinctive) feature, binary opposition, markedness, redundancy, structuralism, and universals. He also showed the importance for linguistics of child language acquisition, aphasia, poetry, metaphor and metonymy (similarity and contiguity), the act of communication (speech event), the meaning of grammatical categories, typology and universals, and the systematicity of language change. And he pointed out the relationship of linguistics to semiotics, cultural anthropology, literary studies, studies of the brain, neurology, and so forth. Jakobson helped to found Russian Formalism, was a cofounder of the Prague Linguistic Circle, and was a dominant force in American linguistics from the early 1940s onward. He was a leading proponent of Prague functional structuralism and pointed out the importance of all the functions of language (including the poetic function) for linguistic analysis. His work in Prague and then in the US aided the development of functionalist approaches, more generally, pragmatics, sociolinguistics and ethnography of communication, discourse and text analysis, psycholinguistics, neurolinguistics, aphasia studies, structuralist approaches to language change, and geographical linguistics. He also influenced literary analysis, poetics, semiotics, social anthropology, mythology, and folklore. (Most of Jakobson's work is reprinted in his *Selected Writings*. For a one-volume introduction to his work in linguistics, see his *On Language*. For more detail and further bibliography for this article, see Waugh and Monville-Burston, 1990, 2002; see also Bradford, 1994.)

Brief Overview of Jakobson's Life

Jakobson was born in Moscow on 11 October 1896 and died in Cambridge, Massachusetts, on 18 July 1982. While still a student in his teenage years he helped to found the two groups known now as Russian Formalism (a combination of the Moscow Linguistic Circle and the Society for the Study of Poetic Language in St. Petersburg), both of which brought together linguists, literary scholars, and writers (especially, aestheticians and poets of the avant-garde). They insisted on the autonomy of literary studies and called for an imminent analysis of literary works, with a focus on the properties that distinguish literary material from any other kind. In 1920, Jakobson moved to Prague, Czechoslovakia and in 1926 helped to found the Prague Linguistic Circle, the cradle of (functional) structuralism. For the Prague School, language serves for communication and thus its internal structure has to be studied from the standpoint of the tasks it performs. Jakobson first coined the term structuralism in 1929 as a cover term for this viewpoint, and was a leading proponent of this highly influential twentieth-century trend in linguistics, and in many allied humanistic, social, and behavioral fields.

In 1939, Jakobson fled the Nazis and in 1941 went to the USA. He taught at the *Ecole Libre des Hautes Etudes*, New York, from 1942 to 1946 and in 1943 he began teaching at Columbia University. In 1949, he obtained a Professorial Chair at Harvard University. From 1957 onward, he was also an Institute Professor at MIT. He was President of the Linguistic Society of America in 1956 and received the International Prize for Philology and Linguistics in 1980 and the Hegel Prize in 1982.

Structural Phonology, Child Language, and Aphasia

During his Prague period, Jakobson and fellow Russian linguist (Prince) Nikolai Trubetzkoy argued that phonological systems are structural wholes, which have to be studied in terms of their relational properties, and that language change has to be seen in terms of systems. They investigated types of phonological systems and established the study of linguistic affinities between languages – how languages that are geographically and culturally related may acquire linguistic traits in common (see Jakobson, 1971a).

During this time Jakobson also turned his attention to the acquisition of phonology by children and its dissolution in aphasics. His monograph – *Child Language, Aphasia and Phonological Universals* (Jakobson, 1941) – demonstrated that the order of acquisition follows the laws of typology: from universal to nonuniversal, unmarked to marked, simple (optimal) structures to more complex ones. He also showed that aphasic loss follows a reverse order.

Theory of Distinctive Features and Functional View of Sound

In his American period and with the aid of advances in acoustic phonetics, Jakobson developed his famous theory that

phonemes such as /t/ and /d/ in *ten* and *den* and /b/ and /m/ in *bat* and *mat* are not the ultimate (smallest) constituents of language. Rather, the distinctive features are the smaller properties of sound by which phonemes are differentiated from each other. For example, /t/ is differentiated from /d/ as unvoiced (voiceless) versus voiced in many languages, and /b/ from /m/ as oral (nonnasal) versus nasal. Jakobson also defined a small set of such (acoustic-perceptual) features that underlie the phonological systems of all the languages of the world (Jakobson et al., 1952; Jakobson and Halle, 1956; Jakobson and Waugh, 1979). He also showed the relevance of these notions for grammatical meaning, which he decomposed into semantic features (see Jakobson, 1984).

Influenced by communication (information) theory and cybernetics, Jakobson explored more deeply the function of language for communication. He insisted, in particular, that all facets of the speech sound have a function (Jakobson and Waugh, 1979): while distinctive features differentiate between words that are different in meaning, redundant features serve to support and enhance the distinctive features. Other features may show the boundaries of words (configurative), inform about the attitude of the speaker (emotive), or indicate the age, sex, social class, etc. of the speaker (physiognomic).

Since distinctive and redundant features have no positive content, but all other types of signs in language do (including words and sentences), there are two types of signs in language; and language and the genetic code are the only systems to have this kind of structure. This differentiation led to a new dichotomy for language (see Jakobson and Waugh, 1979; Jakobson, 1980): mediacy (elements with an indirect relation to meaning such as distinctive features) versus immediacy (direct relation between sound and meaning: phenomena such as sound symbolism; synesthesia; glossolalia; and mythic, poetic, and magical uses of sound). In many cases of mediacy, there is an iconic (nonarbitrary) relation between sound and meaning (see also Jakobson, 1966). This dichotomy is also related to the hemispheres of the brain (left vs right, respectively) in Jakobson (1980).

All of the feature types together represent the entire makeup of a sound and there is nothing that is pure sound (Jakobson and Waugh, 1979). Consequently, the oppositions traditionally made between linguistic and nonlinguistic, abstract and concrete, functional and nonfunctional, (phon)emic and (phon)etic are inappropriate.

Invariance and Relational Structure

Invariance was, for Jakobson, the dominant topic and methodological device underlying his research: any sign is defined by invariant properties that differentiate it from the other elements in the system of which it is a part. Across languages too, he also insisted on the importance of universal invariants (language universals), establishing the equivalence of diverse signs. In addition, he correlated invariance with contextual variation: any sign evidences variation as it enters specific contexts. Contextual variants are not equal, but hierarchized: some are more basic, others more marginal. Invariance and variation apply to the *signans* (e.g., sound, as in variation across phonemes) and the *signatum* (e.g., the semantic properties of the case and verbal systems of Russian (see Jakobson, 1984)). In semantics, by incorporating invariance (context-independent meaning, general meaning) and variation (context-specific meaning, polysemy, reference), he gave the basis for a rigorous approach to grammatical and lexical meaning.

Invariance for Jakobson was always invariance in relationship (equivalence); and the primary type of relation in language is that of binary opposition, phonological (e.g., nasal vs oral), grammatical (e.g., singular vs plural), or lexical (e.g., 'near' vs 'far'), etc. (see Jakobson, 1971a,b, 1987; Jakobson and Waugh, 1979). Such binarism is based on an asymmetry in the relationship between a marked (focused or weighted) and an unmarked (neutral) term, for example, marked nasal, plural, 'near' vs unmarked oral, singular, 'far.' For Jakobson, markedness is a fundamental way by which we organize not just language but cultural systems in general.

Functions of Language

For Jakobson, the *raison d'être* for language is communication and language is suited to various communicative goals, which in turn are correlated with the act of communication in which language is used. In his famous article, *Linguistics and Poetics*, he defined the six primary factors of any speech event: (1) speaker (addresser), (2) addressee, (3) context (including the thing referred to), (4) message (*parole*, language use), (5) code (*langue*, linguistic system), and (6) contact (medium) of communication. In conjunction with these, he then defined the functions of language in terms of a focus in the message on one of the factors: (1) emotive function (focus on the speaker), for example, intonation showing anger; (2) conative function (focus on the addressee), for example, imperatives and vocatives; (3) referential function (focus on the context), for example, talk about the real world; (4) poetic function (focus on the message), for example, poetry; (5) metalingual function (focus on the code), for example, definitions of words; and (6) phatic function (focus on the contact), for example, 'hello, do you hear me?' These functions may be dominant in a message or may be subsidiary; for example, a referential message may carry expressive information about the opinion of the speaker.

Metaphor and Metonymy: Similarity/Contiguity

In 1956, Jakobson published his famous *Two Aspects of Language* where he analyzed the relation between communicative processes and properties of linguistic structure. First, he distinguished two fundamental operations: selection (substitution) for encoding (production) and combination for decoding (comprehension). Then, he contrasted two types of relations: similarity (all types of equivalence) and contiguity (temporal and spatial neighborhood, causal relations, part–whole), and said that they underlie the two operations. Put simply, the elements in a selection set are normally associated by similarity and those in combination by contiguity. Since in aphasia, the normal patterning of speech is disturbed, Jakobson proposed that these factors be used as a way of categorizing types of aphasic disturbances.

For Jakobson similarity/contiguity is a fundamental polarity of language, texts, culture, and human thought (cognition) in

general. He used it for much of his work in semiotics of film and music. He also used it to refine his definition of the poetic function (1960): in poetry, where focus on the message is dominant, equivalence (similarity) relations are used to build the combination rather than only to underpin the elements of the selection set. Thus, rhyme, alliteration, parallelisms, metaphor, etc. help to structure the poetic text, whereas in prose contiguity is the essential constructional principle.

Grammar

Jakobson also focused on the function of grammatical categories. His famous article on *Shifters* (1957) focuses on those elements whose general meaning in the code can only be specified by taking into account their use in messages, because the codal meaning includes information about particular elements of the speech event. For example, deictic pronouns designate speaker (I) and addressee (you). Thus, language encodes pragmatic factors of the context of utterance and linguistics necessarily includes syntax, semantics, and pragmatics.

Grammatical categories (both morphological and syntactic), for Jakobson (citing Franz Boas), are defined as those which are obligatorily present in the construction of acceptable messages (1959a,b), whereas particular lexical categories (e.g., words referring to space) are optional. Through this view of grammar, Jakobson provided a semantic and operational approach to the relation between language and cognition: grammatical categorizations provide the necessary patterns of thought.

Jakobson was also inspired by Charles Sanders Peirce's notion that the essence of a sign is its interpretation, that is, its translation by some further sign. Henceforth, he defined the *signatum* as that which is interpretable or, better, translatable (Jakobson, 1959b) by a potentially unlimited series of signs. He characterized the Peircian approach as the only sound basis for a strictly linguistic semantics.

Jakobson's Legacy in Linguistics and Other Fields

Jakobson's influence on twentieth-century thought was considerable and many of his contributions have become a permanent part of American and European views of language. He has had such a towering role in linguistics that his work has defined the field itself. Many of Jakobson's concepts and discoveries are now so deeply ingrained in the theoretical basis of modern linguistics that they are thought to be commonplace or self-evident. This article will consider, in particular, his influence on linguistics in the last 30 years or so and later offer some brief notes on other disciplines. (For more details of Jakobson's influence, see Waugh and Monville-Burston, 1990, 2002.)

Influence on Linguistics

Jakobson's view of language as a relational whole and a communicative tool with many functions opened the door to functionalist approaches more generally, and abetted the development of linguistic studies that look at discourses and texts and consider their wider linguistic and 'real-world' environment. His work on *Shifters* showed that grammar, semantics, and pragmatics are but different sides of the same phenomenon and aided present-day interest in pragmatics. Work in pragmatics has led linguists to explore the boundaries of their discipline with the neighboring fields of anthropology, sociology, mythology, philology, and philosophy in a truly Jakobsonian interdisciplinary spirit. His writings on grammatical meaning have inspired others to investigate the interdependence of invariance and variation, the semantics of case systems, and the interrelation of tense and aspect with syntax, discourse, and the lexicon.

Jakobson's insistence that language is a complex and dynamic whole with a variety of subcodes (speech styles) helped to pave the way for the advent of sociolinguistics. The ethnography of communication has also taken its inspiration from Jakobson's multifunctional perspective on communication. His work on the functions of language and their relation to the speech (communication) act remains central in the investigation of speech in interaction. Anthropological linguists – who adopt a functional and pragmatic perspective with an interest in folklore, poetics (oral traditions), and discourse analysis – draw on and develop the ideas of the Prague School and Jakobson in particular.

Jakobson stressed the need to search for general laws governing all linguistic systems and thus helped to foster the current interest in generalizations. He saw a definite equivalence between the search for explanatory adequacy in generative grammar and the elicitation and interpretation of the entire network aimed at by Prague structuralism. His monograph on child language and aphasia, generally regarded as one of his most original and influential works, has been signaled as the point of departure of a new era in linguistics and has been lauded by many because it showed the relation between child language and phonology, launched psycho- and neurolinguistics, and ushered in a new focus on universal and law-governed, general (explanatory) properties of language.

The widespread movement that presently investigates universal properties of language, both universal grammar and language universals, is deeply indebted to Jakobson. When the linguist Noam Chomsky came in contact with Jakobson and worked with Jakobson's student and coauthor Morris Halle, he fully realized the explanatory power of universals and their relation to language acquisition; thereafter, he set out to determine universal constraints on the form of grammars. The other stream of research in universals, practiced by Joseph Greenberg and his associates, examines concrete materials from a great variety of languages in order to establish typological classifications and establish empirically the general laws that underlie the structure of human language.

Many scholars agree with Jakobson that typology is important for the study of language change, areal linguistics, and historical reconstruction. His work in historical, geographical, and areal linguistics continues to be reprinted in readers in these areas. The seminal idea that changes must always be treated in view of the system that undergoes them is the essential premise for textbooks in historical linguistics. And Jakobson's view of the teleological basis for language change has been instrumental in inspiring further work.

By revealing the close relationship between developmental studies and vital questions of linguistic theory, Jakobson's *Child Language* also launched psycholinguistics. Many psycholinguists now recognize that the broad outlines of this bold synthesis continue to be confirmed. Following Jakobson's example, scholars interested in language pathology have studied aphasia from a linguistic point of view and, for many, Jakobson's distinction between similarity disorders and contiguity disorders is regarded as fundamental, and firmly supported by contemporary ideas of the functional organization of the human brain. Jakobson was the first modern linguist to investigate in depth the concurrent constituents of linguistic elements. Many linguists have claimed that the distinctive feature was Jakobson's greatest insight and, after the phoneme, the most significant step forward in modern phonology. Generative phonology recognizes Jakobson as one of its founding fathers, in particular, through Halle. Markedness and the correlated notion of binary opposition are now widely used in linguistics and other disciplines. Componential analysis – analyzing an item into smaller properties and representing them as a combination – was generalized as a methodological model for semantics and lexical representation, and has been adopted in other approaches as a means of describing the structure of a variety of semantic fields.

Influence on Other Fields

Jakobson's influence on contemporary thought has also spread to disciplines such as literature, poetics, semiotics, social anthropology, mythology, and folklore. His theoretical papers *Linguistics and Poetics* and *Poetry of Grammar and Grammar of Poetry* and his analytical studies of poems by Baudelaire and Shakespeare (as well as many other poets in many other languages) established him as an important theoretician of literature (see Bradford, 1994). He is the source of not only structuralist but also other contemporary trends in literary theory. He also helped to develop semiotics as a discipline in its own right and has been called the major catalyst in the contemporary semiotic reaction (see Jakobson, 1973). And he is credited with introducing the American semiotician Charles Sanders Peirce to Americans and with showing them the importance of Peirce's insights. His work in semiotics has also had repercussions in fields as diverse as economics, mathematics (especially catastrophe theory), sociology, and philosophy.

Jakobson's influence on anthropology is considerable. In American anthropology, for example, three convergent Jakobsonian ideas have proven to be particularly fruitful: the structure of the poetic text, the closeness of ties between poetry and mythology, and the relationship between discourse and cultural context. His greatest impact, however, has been on structural anthropology, especially through Claude Lévi-Strauss, who considers himself a disciple of Jakobson and has repeatedly acknowledged his indebtedness to him. He used many Jakobsonian ideas in his work on kinship systems, cooking, folktales, myths, and primitive thought.

With the breadth and depth of his knowledge, his brilliant imagination, his prodigious output, the originality of his accomplishments, and his international influence on a variety of fields, Roman Jakobson has been recognized worldwide as one of the major creative minds of the twentieth century.

Abstract

William James, American philosopher and psychologist, remains a vivid presence in psychology because of his two classics, *Principles of Psychology* (1890/1981) and *Varieties of Religious Experience* (1902/1985). His work at once embodies the culmination of nineteenth century psychology, in his critical review of the older philosophical psychology and of the new experimental psychology, and the launching of twentieth century psychology, especially the functionalist tradition. He is remembered in philosophy as one of the last philosophers in the grand style who also sought to communicate his insights to a broad audience, an audience attracted by the informal felicity of his writing, public lecturing, and teaching. Distinctively American in his promotion of a pragmatism that viewed abstract concepts critically in terms of their 'cash value,' he participated actively in the European intellectual scene and, like his eminent novelist brother Henry James, advanced the linkage of the American and European intellectual and cultural worlds.

William James, American philosopher and psychologist, remains a vivid presence in psychology because of his two classics, *Principles of Psychology* (1890/1981) and *Varieties of Religious Experience* (1902/1985). His work at once embodies the culmination of nineteenth century psychology, in his critical review of the older philosophical psychology and of the new experimental psychology, and the launching of twentieth century psychology, especially the functionalist tradition. He is remembered in philosophy as one of the last philosophers in the grand style who also sought to communicate his insights to a broad audience, an audience attracted by the informal felicity of his writing, public lecturing, and teaching. Distinctively American in his promotion of a pragmatism that viewed abstract concepts critically in terms of their 'cash value,' he participated actively in the European intellectual scene and like his eminent novelist brother Henry James advanced the linkage of the American and European intellectual and cultural worlds.

His enduring significance at the end of the twentieth Century is reflected in the publication of definitive scholarly editions of his complete writings in 17 volumes (1975b–88) and of his correspondence (1992) of which 12 volumes were planned. As members of an unusually creative family, he and his brother Henry and sister Alice have been the subject of extensive biographical attention (e.g., Lewis, 1991; Myers, 1986; Perry, 1935).

Family Background and Early Life

The James family was economically privileged. William's father, Henry James Sr. (1811–82), who had inherited a comfortable living, was a restless, questing intellectual who found inspiration in the writings of the Swedish mystic Emanuel Swedenborg. He attracted visits from the New England transcendentalists Emerson and Thoreau while William was an infant in New York City, where he was born 11 January 1842. William's education was irregular, including periods of schooling or tutoring in England, France, Germany, and Switzerland. The intense moral and intellectual climate of the family seemingly entailed severe costs in physical and mental health for William and his gifted siblings. Teasing out the sources of creativity and of pathology in the James family has challenged its biographers.

When William was 18, he embarked on the study of painting in the Newport studio of William Hunt, a prominent American artist. But he gave up painting after about 6 months, turning next to science. He pursued studies in chemistry and comparative anatomy at Harvard, and, in a smaller shift in direction, entered Harvard Medical School when he was 22. These were years of increasing doubt, depression, and psychosomatic discomfort. James interrupted his medical training for a year to take part in an expedition to the Amazon with the Harvard biologist Louis Agassiz, and interrupted it once more to spend a year and a half in Germany taking therapeutic baths and reading widely in German literature, philosophy, and science. Returning to complete his M.D. degree in 1869, he spent several years of mental distress and near collapse living with his parents.

It was during this period that, by his own account, he drew on philosophy in a turn toward recovery, as he recorded in a subsequently famous passage in his diary of 30 April 1870:

> I think that yesterday was a crisis in my life. I finished the first part of (Charles) Renouvier's second *Essais* and see no reason why his definition of free will – 'the sustaining of a thought because I chose to when I might have other thoughts' – need be the definition of an illusion. At any rate, I will assume, for the present – until next year – that it is no illusion. My first act of free will shall be to believe in free will (Perry, 1935, vol.1, p. 323).

This passage heralds the theme of voluntarism that pervades his later writings, as well as suggesting roots of his pragmatic philosophy.

James's productive life began in 1873 when he was appointed instructor in anatomy and physiology at Harvard. By 1875 he was teaching his first course in psychology, in connection with which he established a teaching laboratory that, as American historians of psychology like to note, preceded Wilhelm Wundt's laboratory at Leipzig in 1879,

a date often enshrined as the founding of scientific psychology. By 1878, when he was 36, he had contracted to write the textbook on psychology that was not to see publication until 1890. It was also in 1878 that he married Alice Gibbens, a teacher who shared his intellectual and spiritual interests and had spent 5 years in Heidelberg with her widowed mother. This event reflected the stabilization of his personal life and also contributed greatly to it. In the following year he offered his first course in philosophy. He was effectively launched in his dual career as psychologist and philosopher at Harvard where he remained for the rest of his life. He died on 26 August 1910, at his family retreat at Chocorua, New Hampshire.

Major Themes

Three themes pervade James's contributions to psychology and philosophy. One is his commitment to voluntarism, the primacy of human agency, which led him to reject mechanistic doctrines. A second is his continual struggle to find a place for religious spirituality as exemplified by his father in the world revealed by Darwinian science. The third, an essential ingredient in his handling of the first two, is his commitment to pluralism and openness in theorizing, as shown in his distaste for abstract systemization and in his opposition to what he saw as the absolutism of both scientific materialism and Hegelian idealism. These themes characterize James's thought throughout his career as psychologist and philosopher, but in the spirit of the third theme, paradoxical inconsistencies recur in his psychology and philosophy.

James's Psychology

In his great book, *The Principles of Psychology* (1890/1981), James presented an account of mental life in the positivistic spirit of natural science. That meant for him that speculative entities beyond experience like the soul or psychological faculties were to be avoided. He took a commonsense dualism of mind and body for granted, though he was explicit that fundamental metaphysical issues would have to be faced eventually. The principal psychological method for him was introspection, by which James mostly meant the informal and avowedly fallible self-observation that he did so well, not the disciplined and quantified introspection of the new German experimental laboratories, which he respected while noting wryly that the method 'could hardly have arisen in a country whose natives could be *bored*.' (p. 192).

James's Functionalism

To apply a term that emerged with his immediate American successors, James was presenting a functional psychology, in the senses subsequently intended by the Chicago functionalists. His focus was on mental processes (functioning), not on the analysis of mental contents into constituent sensory elements. Further, he emphasized the adaptive functions of psychological processes, in line with evolutionary theory. Consciousness, he proposed, emerged to organize and direct neural processes in the brain that had become too complex to be guided by a mechanistic concatenation of reflexes. His vision of scientific psychology was committed to a mind–body interactionism troublesome to both scientific materialists and philosophers.

James viewed the nervous system and the brain as organs of mind, and devoted early chapters of the *Principles* to the functions of the brain. There follows a chapter on habit, foreshadowing the later preoccupations of J.B. Watson's behaviorism. James's account of habit was primarily physiological. Currents in the cerebral cortex originating in the sense organs 'leave their traces in the paths which they take. The only thing they can do … is to deepen old paths or to make new ones. … (A) simple habit … is, mechanically, nothing but a reflex discharge; and its anatomical substratum must be a path in the system' (p. 112). From this physiological base James proceeded with recommendations for the cultivation of good habits, putting neural mechanism to voluntary use for moral purposes, a characteristically Jamesian manoeuver.

The Stream of Thought

If James's treatment of the brain and of habit pointed toward later developments in neuropsychology and behaviorism, his classic treatment of the stream of thought provided a sensitive and persuasive alternative to the prevalent approaches of introspective psychology that sought to decompose ideas and images into sensory elements. For James, the proper starting point in psychology is not sensations or feelings, as in prevalent elementaristic psychologies, but the sheer fact that thought goes on. 'Every thought tends to be part of a personal consciousness,' he wrote (p. 220). Thought seems continuous but is always changing. It deals actively and selectively with objects independent of itself. The idea that thought is actively selective underlies James's later discussion of attention, which in turn provides the rationale for his treatment of will, in terms of holding a thought of action in focus long enough for the action to occur.

No two states of consciousness are ever the same. 'A permanently existing "idea"... which makes its appearance before the footlights of consciousness at periodical intervals is as mythological an entity as the Jack of Spades' (p. 230). Relationships and transitional states are given in the primary data of introspection just as directly as the more substantive states on which consciousness may momentarily 'perch.' James's views here anticipated those of the Würzburg school regarding imageless thought, and foreshadowed Gestalt psychology in their rejection of sensory elements. James's evocative term, 'the stream of consciousness,' found a place in the context of world literature.

The Consciousness of Self

Since the stream of thought is always a personal consciousness in which the objects of awareness are divided into 'me' and 'not me,' James followed his treatment of the stream of thought with a chapter on 'The Consciousness of Self' that was very influential on later scholarship. If 'I' is taken to label the person as agent and introspective observer, 'me' is the self as object of introspective observation. For the purposes of his psychology, the 'I' is simply the passing thought in the personal stream,

which appropriates the person's memories of the past and anticipations of the future. The 'me' comprises a hierachy of three selves. First is the material self – one's body, clothes, and the material possessions that one regards as 'mine.' The social self, or more properly, selves, consists of the views of oneself held by others that one cares about, as one understands them. The spiritual self is 'a man's inner or subjective being, his psychic faculties and dispositions, taken concretely … the most enduring and intimate part of the self' (p. 283). These three aspects of 'me' are the focus of motives of self-seeking and self-preservation, and of self-feelings of self-complacency and self-dissatisfaction. James provided a famous 'formula' for self-esteem as the ratio of Success to Pretensions, anticipating much later research and theory about Level of Aspiration.

The distinctively human attribute of reflective self-awareness highlighted in James's treatment of selfhood was subsequently developed mainly by social psychologists in the sociological tradition, especially C. H. Cooley and G. H. Mead, but returned as a central concern of psychologist students of personality and social behavior in the latter half of the twentieth century.

Emotion

Of all the special psychological topics that James discussed, his theory of emotion evoked more notice and controversy than any other. It was known as the James–Lange theory because in the *Principles* James linked his ideas as previously published in the 1880s with similar views of the Danish physiologist Carl Georg Lange published at about the same time. James's version held that the stronger or 'coarser' emotions of grief, fear, rage and love arise from feeling bodily changes that are aroused directly by an 'exciting fact.' In contrast with folk belief, we do not weep because we feel sad; we feel sad because we are weeping. We feel fear because we are set to run away. We feel because we act.

During the first half of the twentieth century, the James–Lange theory did not fare well. In one important critique, the physiologist Walter Cannon showed in animal research that centrally mediated emergency emotional responses do not depend on feedback from the viscera, a finding that bore more critically on Lange's version of the theory than on James's. More importantly, in a period dominated by behaviorism, James's central interest in emotion as conscious feeling seemed scientifically irrelevant. With the subsequent decline of behaviorism, each of several competing treatments of emotion looked back to James as anticipating their conclusions. Paul Ekman and Carroll Izard focused on the role of sensory feedback from the facial musculature in emotional expression as crucial to the distinctiveness of felt emotions, whereas Stanley Schachter launched a cognitively focused line of research emphasizing the interpretive context in which arousing stimulation is encountered. As cognitive perspectives on human psychology developed one-sidedly, James's emphasis on the centrality of feeling became more attractive.

Other Aspects

As embodied in the *Principles*. James's psychology dealt with many other topics, some familiar in later textbooks, others less so. At first encounter, James's account of the will seems foreign to present students of psychology, who are accustomed instead to nonconsensual chapters on motivation. For James, voluntary movements are a secondary development from the primary organic functions involved in reflex action, instincts, and emotional movements (p. 1099). The link between thought and voluntary action is provided by ideo-motor action, the concept that thoughts of a movement lead directly to making the movement, unless contrary inhibiting thoughts intervene. With the resurgence of cognitive and neuropsychology, James's focus on the selectivity of attention and on the relation between thought and action returned as central to the discipline. His century-old formulations are no longer useful, but his identification of significant problems for psychology earns renewed respect.

Other topics broached in the *Principles*, particularly hypnosis and divided consciousness, anticipated concerns beyond the boundaries of positivistic science that continued to preoccupy James during his mainly philosophic period that followed its publication (see Taylor, 1983). James was much interested in the work of the French psychopathologists Charcot, Janet, and Liébeault, who preceded psychoanalysis in giving attention to nonrational processes outside the scope of normal consciousness.

James as a Philosopher

In spite of James's expressed intent in the *Principles* to avoid metaphysics, the book was infused with his philosophic thinking, particularly in his critique of earlier philosophic psychology, and contains the germ of most of the philosophic positions on which he elaborated subsequently. His specific impact on philosophy is identified with pragmatism and radical empiricism. Pragmatism, launched by James, became a vigorous philosophic movement which enjoyed a renaissance late in the twentieth century. Radical empiricism was James's attempt at the fundamental metaphysical construction that he postponed in the *Principles*. The work was incomplete at the time of his death, and the book presenting it (James, 1912/1976) was assembled posthumously from journal articles.

Pragmatism

When James published *Pragmatism* (1907/1975a), a popular book that was much reprinted and translated, he drew on his earlier writing and thinking over three decades. Here, he offered the pragmatic method as a way of settling metaphysical disputes that might otherwise be interminable, such as those between tenderminded religious and toughminded materialistic world views: 'The pragmatic method … is to try to interpret each notion by tracing its respective practical consequences. What difference would it make practically to anyone if this notion rather than that notion were true?' (1907/1975a, p. 28) The pragmatic method entails a perspective on meaning. As he writes, 'to develop a thought's meaning, we need only determine what conduct it is fitted to produce: that conduct is for us its sole significance' (p. 29). And with pragmatic meaning comes a pragmatic conception of truth, as characterizing beliefs

that receive confirmation when acted upon. 'The truth of an idea is not a stagnant property inherent in it. Truth *happens* to an idea. It *becomes* true, is *made* true by events. Its verity *is* in fact an event, a process …' (p. 97). With characteristic generosity, James attributed his initial ideas about pragmatism to his friend the semiotic philosopher C. S. Peirce, who did not agree with James's developed approach.

The extensive philosophical controversy about pragmatism in the first decade of the twentieth century appears to reflect considerable mutual misunderstanding on the part of both James and his critics, as well as some problems with his mostly informal exposition (see Myers, 1986). He can be interpreted as treating claims of pragmatic truth as similar to the provisional truth claims of empirical science, in the spirit of Peirce and, later, John Dewey, or alternatively, as rationalizing wishful thinking (religious faith has good personal and social results, so it may be accepted legitimately as true by its believers). The idea that philosophical abstractions and assertions should be judged in terms of their practical consequences came to seem typically American, to both his supporters and his critics.

Late in the twentieth century, interest in pragmatism revived, with similar diversity of interpretation. One strand of thought prominently represented by the philosopher Rorty (1979) became part of the 'postmodernist' attack on the scientific world view to which some disaffected psychologists subscribed. Knowledge, in this version, is a human construction for human purposes and cannot be taken as a 'mirror of nature,' a view with roots in James. Some other humanistically inclined applied psychologists called for a pragmatic psychology focused on useful contextually limited truths rather than general laws. This version of pragmatism retains a commitment to evidential empiricism like that of the early James.

Radical Empiricism

As James entered his final decade increasingly troubled by his failing heart, he turned to the fundamental metaphysical issues that he had tabled when he wrote the *Principles*. In pragmatism, he had crystalized a theory of knowledge developed over his full career. Radical empiricism, in contrast, proposed an ontology that continued his attack on Hegelian absolute idealism but broke sharply with the commonsense mind–body dualism of his scientific psychology. To transcend this Cartesian dualism, and the cognitive dualism of thought and its object or consciousness and its contents, he now proposed pure experience as the fundamental reality. Pure experience prior to analysis or conceptualization does not distinguish between thing and thought. The commonsense categories, he believed, could be recovered from the contexts in which ingredients of pure experience are embedded and their various relationships. His apparent move toward philosophical idealism was qualified by his continuing commitment to pluralism: '… there is no *general* stuff of which experience at large is made. If you ask what any one bit of pure experience is made of, the answer is always the same: "It is made of *that*, of just what appears, of space, of intensity, of flatness, brownness, heaviness, or what not"' (1912/1976, p. 14–15).

Religion and Psychic Research

James continually struggled to find a place for the moral and hopeful view of humanity's place in the universe that religions can provide. Pragmatism was one route through which he sought to reconcile the world views of religion and science. Another was psychic research. For two years he was president of the Society for Psychical Research, to which he belonged from 1884 until his death. He was ever hopeful of finding supportive evidence for spiritual realities, and never satisfied that the evidence actually obtained was adequate (cf James, 1986).

James was already esteemed as a leading philosopher and psychologist when he delivered invited lectures on 'natural religion' at the University of Edinburgh in 1901–02. Their publication as *Varieties of Religious Experience* (1902/1985) became his second enduring classic, one that, a century later, is not only cited and respected but also read. Displaying the meaning of religion in the religious experience of individuals, it draws richly on accounts by saints, mystics, and others who provide evidence of their relation to what they regard as the Divine. The conceptual distinctions around which he organized his description and analysis have entered our common culture: the religion of healthy-mindedness vs. that of the sick soul; the 'divided self' and 'once-born' and 'twice-born' characters.

Although his sympathetic feeling for the many forms of religious belief is clear throughout, his presentation of religious experience is rightly esteemed by believers and unbelievers alike. His way of deploying 'case materials' to display the nature of a human phenomenon is a model for contemporary qualitative research to emulate.

James regarded the subconscious mental states revealed by the French psychopathologists as important in religious conversion. Speculatively, he declared his conviction that subliminal consciousness overlaps other realms of consciousness in mystical experience. By 'being faithful in my poor measure to this over-belief, I seem to myself to keep more sane and true' (1902/1985, p. 408). Here, James made radical and pragmatic use of his developing 'radical empiricism.' In the late twentieth century, this mystical side of James appealed to disaffected psychologists identified with a 'transpersonal' psychology with religious undertones.

On Public Issues: Imperialism and War

As a public intellectual, James was involved in the social issues of his day. A political as well as a philosophic liberal, he was opposed vehemently to emerging American imperialism in the wake of the Spanish American War. It was as an advisor to the peace movement that he wrote *The Moral Equivalent of War* (1910/1982), one of his last essays published in his lifetime, which remains a classic document in the psychology of war and peace.

After an evolutionary account of human warlike propensities, he noted that the militarists of his day held warfare to be the mainstay of admirable, martial virtues, and that as a 'pleasure economy' supplants the earlier 'pain and fear economy,' these virtues are likely to degenerate. He agreed that war fosters 'manliness' and surrender of private interest, but, given the

monstrosity of modern war, he proposed planning for alternative sources of energizing challenge. Specifically, he suggested 'instead of military conscription a conscription of the whole youthful population to form for a certain number of years a part of an army enlisted against *nature* ...' (p. 171). That he focused on 'manliness' and cast nature in the role of enemy shows James as a creature of his time, but his idea of the moral equivalent of war remains attractive. The equivalence is not in regard to the release of aggression, however, but to self-testing for the common good against difficult challenge.

William James Today

James's vivid and unconventional writings assure his continued influence, as they won him acclaim but evoked controversy in his lifetime. In North American psychology, James has become such a revered ancestor that his name gets called upon in many divergent contexts. His pragmatism is still very much alive. At one point, James considered humanism as an alternative term to pragmatism. Certainly, the influence of James in psychology and philosophy has favored humanistic responsiveness to the richness and variety of human experience, in contrast with the abstractness of absolute idealism in his own day and the dehumanized barrenness of behaviorism, logical positivism, and analytic philosophy that followed. His sensitive phenomenological treatment of thought and self remains unsurpassed, though it has been built on and superseded in various ways. His openmindedness and pluralism set a valuable counter-ideal to the dogmatism that is always a potential liability of mainstream doctrine. This counter-ideal inspired mid-century psychologists of personality such as Gordon Allport, Gardner Murphy, and Henry Murray. At the turn of the millenium, it further inspires transpersonal psychologists who find in James respectable company for their own tendencies toward mysticism. The controversy surrounding James continues.

Abstract

Pierre Janet, French psychologist and psychiatrist, was among the first to develop a dynamic psychology using the concepts of subconscious ideas and psychological force. Janet contributed to the understanding of hysteria and of obsessive-compulsive disorders through his theories of dissociation and psychasthenia. His etiology of mental illness stressed both constitutional weakness and the role of traumatic memories. His method, 'psychological analysis,' moved beyond an early reliance on hypnotherapy to include intensive case study and the recovery of dissociated traumatic memories. In many ways, Janet can be ranked with Sigmund Freud as one of the great systematic thinkers in the history of psychology.

Pierre Janet, pioneering French psychologist and psychiatrist, was born 30 May 1859 in Paris. He studied philosophy at the elite *Ecole Normale Supérieure* and began his career teaching philosophy in aprovincial *lycée*. While teaching at Le Havre from 1883–89, he worked with local physicians to conduct experiments on hypnosis with hysterical patients. These experiments led to several publications, including the thesis for his doctorate in philosophy, *L'automatisme psychologique* (1889). In the same year, Janet obtained a position teaching in a Paris *lycée* and began formal training in medicine. He worked at the Salpêtrière hospital under the direction of the foremost authority of the day on hysteria, the neurologist JeanMartin Charcot. Janet received his medical degree in 1893 and continued to work at the Salpêtrière until 1910. The cases he studied there formed the foundation for some of his most important works. In 1902, Janet was named to the chair of experimental psychology at the Collège de France, where he taught until 1935. He also co-founded and edited the *Journal de psychologie normale et pathologique*. He died on 24 February 1947 in Paris.

Janet's thought can be separated into an early and a late period, with 1910 as a rough dividing line. In the early period, which was by far the more influential, Janet focused on extending the domain of mental life and on elaborating a psychology based on a distinction between automatic and synthetic mental activity. As a result of his investigations into hypnotism and post-hypnotic suggestion, Janet rejected the then-common assumption in scientific and medical circles that unconscious mental functioning was physiological in nature. He insisted that it depended on the intervention of ideas, just as conscious mental functioning does. These ideas simply are not connected with the consciousness of the self. Because the word unconscious implied 'neurological' for so many at the time, Janet coined the term 'subconscious' to characterize ideas separated from consciousness.

The distinction between automatic and synthetic mental activity separated Janet from British associationist psychology. Janet held that association could only recall connections previously established by the mind; in other words, association explained automatic functions such as habit and conditioned response. Associations initially are established by mental synthesis, which combines the disparate elements of perception into related wholes. Synthesis is the basis for the integration and interpretation of experience. Beginning at the simplest level of combining sensory data into perceived objects, synthesis works on its own products to build ever higher levels of object, culminating in the concepts of the self and the world. By conceiving the self as the product rather than the origin of synthetic activity, Janet rejected the traditional Cartesian notion of the self as simple and primary; rather, the self is one of the most complex mental phenomena, and it appears only at an advanced stage of mental development. In addition, Janet dismissed the philosophical tendency to characterize abstract reason as the pinnacle of human mental functioning. Influenced by evolutionary theory, Janet insisted that adaptive behavior in the real world required the greatest mental effort and that, in the real world, the social world posed more challenges than the natural world.

Synthesis requires energy, which Janet characterized through a concept of psychological force. An individual's psychological force determines the quantity of psychological stimuli they can hold together in synthetic unity. To describe the quality or level as well as the quantity of synthetic activity, Janet developed the idea of psychological tension. When individuals lose psychological force, they can no longer synthesize all of the stimuli impinging upon them. The inability to integrate perception leads to various kinds of mental illness, which Janet grouped into two major classes. One was hysteria, in which sufferers respond by abandoning or dissociating whole classes of perception. They may lose consciousness and control of parts of their body (producing hysterical paralysis), memory (amnesia), or behavior patterns (tics and fugues). In extreme cases, synthesis continues to operate on the dissociated portions of mental life beyond the awareness or control of the self, producing what was then known as double consciousness and what today would be called multiple personality or dissociative identity disorder.

To describe the other major class of mental illnesses, Janet coined the term 'psychasthenia,' which he used instead of the existing term 'neurasthenia,' to emphasize the psychological rather than biological nature of the condition. Psychasthenics retain consciousness of their uncontrollable thoughts and actions even as they are powerless to stop them. Such individuals suffer from obsessive-compulsive disorders and from feelings of inadequacy related to their inability to control themselves.

Janet attributed the lack of psychological force to two main causes – constitutional deficiency and traumatic emotions. Following in a long hereditarian tradition, Janet held that some

people are born with less psychological force than others. Such individuals are more prone to mental illness, because they are more likely to be overwhelmed by the external world. In addition, traumatic incidents may produce emotions that sap energy and disrupt the normal process of synthesis. Individuals lose the ability and the desire to integrate into consciousness painful memories, which continue to play a disruptive role as dissociated subconscious ideas.

Janet's treatment of patients began with what he called 'psychological analysis,' during which the therapist attempts to separate symptom complexes into their elements and to uncover the origins and development of the ideas behind these elements. Janet used a variety of techniques in psychological analysis. He began his career relying heavily on hypnotism to reveal subconscious memories and dissociated personalities. He supplemented hypnotism with automatic writing and other techniques designed to elicit responses from the patient's subconscious. Such methods had limitations, however. Janet became sensitive to issues of suggestion in the production of hysterical symptoms. Indeed, he was one of the first historians of hypnotism, tracing the origin of the classic hysterical symptoms described by Charcot to the effects of earlier magnetizers on the patients Charcot examined. Janet also found that psychasthenics tended to be less susceptible to hypnotism. He came to rely more on repeated observations of and conversations with the patient over long periods. Through this interaction, Janet was able both to discover the origins of neurotic symptoms and to establish a relationship with the patient that would aid in the therapeutic process.

Once the origins and elements of the symptoms were discovered, Janet attempted to eliminate their pathogenic effects by a variety of methods. By enabling patients to reintegrate dissociated memories into consciousness, Janet was able to reduce their disruptive power. He also tried to dissolve such memories through suggestion and substitution. One case he reported was that of Justine, who had hysterical crises provoked by an intense fear of cholera. Through analysis, Janet discovered that as a child Justine had developed a fear of death by helping her mother, who was a nurse, care for dying patients. This fear was further focused by an incident in which Justine saw the putrefying corpses of two cholera victims. Janet recovered these memories, and then, through an elaborate and gradual process of suggestion, substituted more acceptable images – a Chinese general with the name Cho-le-ra for a diseased corpse. Eventually, the word cholera lost its power, and the symptoms disappeared.

Janet also tried various measures to adapt a patient's psychological force to the demands of her or his environment in order to prevent a recurrence of symptoms and to avoid the development of new illnesses. He used mental exercises to increase the patient's psychological force and recommended reductions in the stresses imposed by the patient's occupation and social life. Though powerless in most cases to change the sufferer's situation, Janet recognized the significance of environment in contributing to the onset of mental illness.

After about 1910, Janet began to redescribe his psychology in terms of conduct rather than ideas. He did this because he came to view the proper goal of psychology as the explanation of the adaptation of the organism to its environment. Ideas are instruments that lead to adaptive action. Janet also expanded and systematized his conception of the hierarchy of psychological levels. In addition, he became increasingly interested in the psychology of religious belief. These new directions came together in his most important late work, *De l'angoisse à l'extase* (1926), based largely on a case study of a highly religious patient with hysterical symptoms.

Janet's influence was considerable at the end of the nineteenth and beginning of the twentieth centuries. His concepts of dissociation and of subconscious ideas found adherents from Carl Jung to William James. Alfred Adler acknowledged his indebtedness to Janet's analysis of feelings of inadequacy. Jean Piaget cited Janet's work on the levels of psychological activity as inspiration for his own developmental theory. In 1906, Janet gave a series of lectures at Harvard Medical School, which made him better known in the US.

However, Janet's influence diminished rather than grew with time. Janet failed to train many followers. He also suffered in competition with Sigmund Freud. Not only was Freud more adept at forming a devoted following, he was more successful at defending the issues over which he differed with Janet, such as the sexual etiology of neuroses and the origin of repressed memories in fantasy. The rise of behaviorism, which despite its focus on action owed little directly to Janet, also eclipsed Janet's own psychology of conduct. In psychiatry, neurological and pharmacological approaches became dominant where Freudian psychoanalysis did not prevail, and in psychology, experimental methods replaced Janet's reliance on psychopathology.

In the last two decades of the twentieth century, a number of psychologists and psychiatrists began to study Janet anew. As Freud's abandonment of the seduction theory was challenged, some found a corrective in Janet's emphasis on actual traumatic events. Theorists who questioned Freud's insistence on the sexual origins of neuroses turned to Janet for a more inclusive view of psychological trauma. The resurgence of dissociative identity disorder as a diagnostic category also led researchers to seek guidance in one of the early students of that condition. Renewed interest in these and other areas to which Janet made substantial contributions assure him an important place in the history of psychology and psychiatry.

Japan: Sociocultural Aspects

Emiko Ohnuki-Tierney, University of Wisconsin, Madison, WI, USA

Abstract

With a primary emphasis on the nonlocalized nature of Japanese culture, this article introduces how almost all features of what we call Japanese culture, including shifting self-identities, were born at the interface of local and global forces. It highlights the internal complexities, comprised of the 'Agrarian Japanese' vs the minorities, those along the lines of gender and age, and overseas Japanese and returnees. The Japanese educational system, religions, health care, youth culture, and sports have all undergone transformations at the confluence of the local and global, showing the dynamic nature of Japanese culture and society.

Shifting political boundaries of the nation-state called Japan, the multiethnic composition of its population, and transnational/global flows involving the Japanese, together with recent epistemological and theoretical questions in various fields, have made anthropological studies of Japan highly complex. Anthropology of Japan, practiced by an increasing number of scholars worldwide, is an enormously active field now that anthropologists are no longer specialists of nonliterate peoples. Neither is it a field for Westerners alone; other Asians are actively engaged in it. After introducing the two dominant schools of anthropology in Japan and a history of anthropology of Japan in the United States, the article points to major developments in contemporary anthropology of Japan including: emphases on minorities and other social groups that had been underrepresented in the past studies; studies on the Japanese not bound to the spatial unit of Japan, including the overseas Japanese, various types of returnees to Japan; studies explicating how almost all features of Japanese culture/history were born at the confluence of local and global forces at present (e.g., youth culture) and in the past (influence of the Chinese and Western civilizations).

A sociocultural overview of Japan appears straightforward. Yet, shifting political boundaries of the nation-state called Japan, its multiethnic composition of the population, and transnational/global flows involving the Japanese, together with recent epistemological and theoretical questions in various fields, have reminded us that such an undertaking is a highly complex enterprise. The anthropology of Japan is a testing ground for new approaches to anthropology, including various attempts to historicize anthropology (Ohnuki-Tierney, 1987, 1993). Following is a brief summary of the field identifying important contributions but focusing primarily on scholarship based in Japan, the United States, and the United Kingdom (see also Hendry, 1992; Eisenstadt, 1996).

Anthropology of Japan: In the Beginning

Anthropology *in* Japan may be represented by two major approaches, both called *minzokugaku*, each having a different character for *zoku*, one referring to folklore or folk traditions, and the other, 'people.' 'Folklore' is equivalent to 'ethnography,' rather than 'folklore' as practiced in the United States. The basic approach was founded by Yanagita Kunio (1875–1962), who emphasized the fieldwork aspect of the discipline. Its emphasis on rural and other marginalized populations was later extended to urban populations under Miyata Noboru (1936–2000). Orikuchi Shinobu (1887–1953), another pillar of this school, made extensive use of classic literature as ethnographic texts, thus introducing history to ethnography.

The other major approach is sociocultural anthropology, which began with the influence of the Viennese school, then turned to British social anthropology, and most recently to American cultural anthropology. Most Japanese scholars in Japan in this tradition specialize in non-Japanese cultures. American anthropology in Japan is largely a product of World War II, when the American government commissioned scholars to decipher its enemy, with a most celebrated, and often criticized, case being *The Chrysanthemum and the Sword* (1946) by Ruth Benedict. Immediately after World War II, scholars focused on 'village Japan,' where they sought a more 'traditional' Japan than modernized city life.

Making the Majority and Marginalizing the Internal 'Others'

Wet-rice agriculture, introduced from the Asian continent to Japan around 400 BCE, gradually supplanted the previous culture, called Jōmon, based on a foraging subsistence economy (Kobayashi, 2003); it provided the political, economic, and symbolic foundation for the Yamato state and the imperial system, which lost its political power after the twelfth century, until it was nominally 'restored' through the Meiji Restoration in 1868.

The rice-based agrarian political economy and cosmology provided a lasting impact on the social structure and cosmological tradition, which became *the* Japanese cosmology *sui generis* for all the Japanese, including non-agrarian peoples. This development contributed to the representation of Japan as 'Agrarian Japan,' writing off many social groups from Japan's history and society. We now see a burgeoning interest in 'minorities' and counter discourses within Japanese society. Since the cultural, linguistic, and biological identities of the

Japanese, Koreans, Ainu, and Gilyaks (Nivkh) remain uncertain, and anthropology no longer recognizes 'race' as such, the question of Ainu identities remains controversial. The Ainu engaged in a foraging economy without a writing system but with a highly developed oral tradition (Ohnuki-Tierney, 1981). Subscribing to the scheme of social evolution, the Japanese as well as Westerners were eager to identify the Ainu as 'primitive hunter-gatherers' or even 'archaic Caucasoids.' Their way of life and physical characteristics were exoticized. As they were colonized by the Japanese (Takakura, 1960), they were forced to abandon their way of life and became a minority, the 'other' within the Japanese nation state. Previously occupying the Kuriles, southern Sakhalin, Hokkaido, and northeastern Honshu, the Ainu are now confined mostly to Hokkaido. Their population peaked at 80 000 in the eighteenth century and then dropped to between 25 000 and 50 000 at the end of the twentieth century. Since the 1960s, various Ainu political groups have made great strides in asserting their indigenous rights.

The so-called *hisabetsu-burakumin* is another by-product of the development of 'Agrarian Japan' (Ohnuki-Tierney, 1987). Until the late medieval period, they constituted loosely defined social groups in non-agrarian occupations dealing with culturally defined 'impurity,' including animal and human deaths, and the visual and performing arts. In 1582, they were codified as 'outcaste,' becoming increasingly marginalized in later periods. Despite legal emancipation in 1870, social discrimination has continued into the twenty-first century. The 1987 government census figures are 4603 districts with a total population of 1 166 733, while the Buraku Liberation League suggests at least 6000 districts with a population of 3 000 000. The Okinawans also constitute a minority whose 'distinctiveness,' if there is any, is based primarily on regional differences. Okinawa's past isolation from the main islands and its location as the gateway of influence from outside created some cultural differences, and their dialect was once regarded as non-Japanese.

There are various 'foreign' residents, of which 85% (700 000) are Koreans. Others include Chinese, Westerners, and more recent immigrants from Southeast Asia and the Middle East. In other words, Japan, although stereotyped as demographically homogeneous, has been a multiethnic nation throughout its history (*see* East Asian Studies: Culture).

Although scholarly work on women had previously been available, studies undertaken at the end of the twentieth century have included feminist and other new perspectives, foregrounding their voices, their life experiences, and women as social agents who actively carve out or change courses of their lives (Hara Chieko, Iwao Sumiko, Karen Kelsky, Takie Lebra, and Ueno Chizuko).

'Culture' – Nonlocalized

Another burgeoning genre of scholarly work derives from an emphasis on how 'culture,' or a particular people such as the Japanese, is not localized. Our awareness of the nonisomorphic nature of culture, locality, and people and an unprecedented flow of population across borders of nation states has led to a number of studies of 'transnationalism' and transnationals in the past and in the contemporary context of globalization. These have included studies of overseas Japanese communities, young Japanese who have returned to Japan after being raised overseas due to their parents' occupation (Goodman, 1990), Japanese businessmen overseas (E. Ben-Ari), and emigrants who have returned to Japan, as well as transnational economic activities (Bestor, 2004). Studies of Japanese colonization have become another powerful lens to understand Japanese culture and society, along with Japanese cultural and political nationalisms (K. Yoshino).

'Culture/History' at the Confluence of the Local and the Global

If the political economy and cosmology of rice agriculture were born as a result of the interaction between the global flow and the local development, so there were subsequent major historical watersheds of Japanese history. Japan's 'modern' era was ushered in because of the threat of Western colonialism all over Asia. In 1868, Meiji oligarchs used the 'return of the imperial system,' whose political power had been virtually nonexistent since the end of the twelfth century, as a means of overthrowing the shogunal government, which had proved incapable of coping with Western threats. The Constitution of Imperial Japan, drafted primarily by German and French scholars, with the Prussian constitution as its model, transformed the emperor from an apolitical deity in the Japanese pantheon to a sovereign, Almighty God, and Commander of the military without, however, practical military power. With Japan's defeat in World War II, a new constitution was written by the American occupying forces, creating a 'symbolic' emperor and introducing equal rights for women, coeducation in public schools, and land reform that drastically leveled economic inequality.

Changes in the educational system too are the result of the local–global interactions. With a high literacy rate, less than 4% of students leave school at the age of 15, while almost all the rest complete senior high school education. Some 500 four-year universities and 580 two-year colleges in the 1990s contrast with the prewar system, which consisted of the National Higher Schools and the Imperial Universities, whose graduates, all male, dominated the key posts in the government, business, and intellectual fields. Today, in addition to the University of Tokyo, University of Kyoto, other major national universities, and the top private universities, such as Keiō and Waseda, there are alternative routes to success, for example, the International Christian University or Jōchi University, run by Jesuits, and Chūō University for law, among others. Holders of doctorates from universities in the United States and United Kingdom receive increasing recognition. A major factor in potential curriculum changes in preuniversity education and also in teacher training is the call for 'globalization' or 'internationalization.' The latest push in this direction is the so-called Global 30, a 5-year program for the internationalization of Japanese universities, begun in 2009 and financed by the government; the program increases the number of foreign students, foreign faculty members, and courses given in English. The initiative was adopted by 13 universities, mostly the top universities, although it has encountered difficulties and opposition, and its future remains

uncertain. Despite democratization of the educational system in some sense, the recent affluence has produced more economically based inequality, with wealthy parents sending their offspring to costly 'cram schools' to increase their chances of passing the entrance examination to prestigious universities (Hendry, 1992).

Late twentieth-century debates over the enforcement of the national anthem and the national flag, textbook revisions, and curriculum changes form an ongoing debate about Japan's military past. After World War II, the American occupation forces enforced the well-known 'blacking out' of passages about Japan's aggression from school textbooks. Half a century later, the Japanese face the problem of how to reintroduce the Pacific war experiences, including atrocities committed by the Japanese military, such as the Nanking Massacre, 'comfort women,' and chemical experiments. In this soul-searching process, the Japanese attempt to locate themselves more solidly among other Asians, rather than upholding Westerners as their mirror, as has been the case in the past.

Culture as a product of local–global interactions is well articulated in Japanese religions. Nominally, the Japanese religions consist of native Shintoism and two religions of foreign origin: Buddhism and Confucianism. In addition, the mountain ascetic practice (*shugendō*) continues to be practiced, while numerous 'new religions' came into being often during periods of unrest. At the end of the twentieth century, several new religions enjoy large memberships, including Sōka Gakkai, which also has formed a successful political party. Mahayana Buddhism came from India via China in the late sixth century; it was first embraced by the elite but later became influential among common people. With the rise of political and military nationalism in the early Meiji period, it was targeted as a 'foreign' religion, and many Buddhist temples and works of art were destroyed. In contrast, Shintoism was 'elevated' to be the exclusive national religion (Hardacre, 1989). These changes at the institutional levels, however, had little to do with the common folk who subscribed simultaneously to Shintoism and Buddhism, both of which had become a part of their daily lives. Most rites of passage celebrating life are Shinto rites, while most mortuary rituals are Buddhist. In Japanese folk religiosity, humans and superhumans constitute a continuum – exceptional humans are assigned power over humans who nonetheless manipulate and cajole the superhumans to their advantage. Japanese religions are decisively 'this worldly,' rather than focusing on salvation after life. The major 'functions' of deities and Buddhas are to provide business prosperity, traffic safety, recovery from illness, good health, success in one's undertaking, including high school and university entrance examinations, and other worldly gains (Kitagawa, 1990(1966)).

Christianity was introduced to Japan when Jesuit missionaries arrived in 1549. The converts were persecuted during the sixteenth and seventeenth centuries, when the rulers saw Christianity as potentially subversive of their authority, and again later during the nationalistic period. At the beginning of Meiji period, American Protestantism was introduced and made a profound influence. Some prominent political and intellectual leaders were converted to Christianity and were highly respected by a broad spectrum of people as pillars of moral conscience under the increasingly totalitarian government. Today, Christianity has penetrated into the daily fabric of the Japanese, with 217 'mission schools' at various levels of education.

Numerous practices that fall under the rubric of 'magic' and 'superstitions' are found in profusion in urban centers and are embraced by a large number of Japanese, including the young and the educated, who carry amulets in their cars and hang them on children's rucksacks and hospital beds. Children and high school students hang votive plaques on which they write a prayer, for example, for success in examinations and dating. Young and old alike practice divination of all kinds when choosing a marriage partner, a date for a wedding, a date for opening of a store, and so forth. Although worldly concerns occupy a central place in Japanese religiosity, at its core is a belief in the soul, especially that of the deceased. Various practices associated with souls of the deceased constitute the most important rituals at the end of the twentieth century. These include funerals and later rituals connected with them, as well as the daily offering of water, tea, freshly cooked rice, and favorite foods of the deceased on their ancestral alcove. Municipalities own large cemeteries where the family tombs of the residents are located. During the Bon festival, when the ancestors are supposed to return to this world, and at other prescribed times, families in cars form caravans to visit these cemeteries. This practice continues in intensity despite the almost complete absence of a vision of the afterworld (Smith, 1974). The belief in the soul – the most fundamental of Japanese religiosity – also explains a long history of an enormous importance of the goblins, ghosts, and related figures in Japanese imagination, paving a way to the more contemporary anime, in which the soul of a doll represents the fluid boundaries the Japanese recognize between humans, nonhumans, and inanimate objects (Komatsu, 2010).

With a population of about 123 million, Japan's demographic pattern is characterized by a large proportion of people over 65 (about 20% at the end of the twentieth century), the world's lowest infant mortality rate, and a very low birth rate. The household, consisting of an extended family with its emphasis on generational continuation and the primogeniture system, has been considered the basic social unit, although it was codified only in the Meiji period and outlawed in 1947. This image is misleading, since the 'continuation' does not mean a continuation through blood lines – a high incidence of adoption characterizes Japanese kinship, and the system was most important only for families with substantial wealth and/or important occupation. For most, the nuclear family has been far more important. Since the mid-nineteenth century, industrialization accelerated the migration of nuclear families to urban centers where well over three-quarters of the population is concentrated today, leaving the rural areas primarily in the hands of the elderly. Since the end of World War II, social structure/hierarchy has undergone significant changes (Ishida and Slater, 2010).

Abortion, legalized in 1948 although practiced with high frequency even earlier, and infanticide were formerly the primary means for birth control. At the end of the twentieth century, the condom (80% of contraceptive users) and the rhythm method are used, with the oral contraceptives legalized only in 1999. In spite of the lowest infant mortality rate in the

world, the Japanese population growth is alarmingly low. The physical and psychological involvement of fathers in child rearing has increased in recent years, so they now spend more time with their families, especially on weekends.

While studies of workplaces by anthropologists are by no means neglected, popular culture now receives much attention (A. Allison; J. Callas; I. Condry; M. Creighton; K. Kelsky; P. Noguchi). 'Globalization' is most visible in 'youth culture,' a product especially of American influence. Whether or not they are in the mainstream of society, today's youth flourish in their youth culture, listening to the latest pop music, following the latest youth fashions, and eating out with their friends at popular restaurants. Many color their hair, sometimes blond. They have adopted body piercing after the fashion of American youth, in contrast to the centuries-old Japanese refusal to imitate Chinese ear piercing, which was seen as a form of impurity. Before the last decades of the twentieth century, even married couples did not show their affection in public. At the beginning of the twenty-first century, public places are crowded with young dating couples who openly display their feelings.

Twenty-first century Japanese, young and old, spend a great deal of money and time on leisure activities, including 'traditional' nature viewing – viewing of cherry blossoms, chrysanthemums, and colored leaves. Television and games constitute the major sources of leisure activity. Sports have become primarily spectator sports watched on TV, with baseball and sumo the most popular. Both professional and high school baseball are enormously popular (Kelly, 2009). Sumo, the oldest professional sport in Japan, received a great deal of attention when it broke with tradition by giving the highest ranking of *yokozuna* to foreign-born wrestlers. There are now sumo organizations throughout the world (Tierney, n.d.). One of the most popular participant sports is golf. Domestic and foreign tourism has become a major leisure activity for Japanese of all ages. The young sometimes combine tourism with their passion for consumerism, going to France, Italy, and the United States to purchase 'brand name' merchandise. A 'unique' leisure activity is the reading of comic books, with some comic books having a weekly circulation of over 4 million – the only arena of recreation competing against the electronic media.

The health care system, too, has developed as a result of Japan's interaction with various others. After the introduction of Chinese medicine, Dutch medicine was introduced during the early eighteenth century, followed by the German system. Today most Japanese go to a biomedical doctor for major acute diseases and surgery, while using Chinese medicine for day-to-day health maintenance and chronic illnesses, in addition to going to temples and shrines to pray for speedy recovery (Ohnuki-Tierney, 1984). In 1959–60, all Japanese became legally eligible for pension coverage and health insurance, provided either by one's employer or the government. During the affluent mid-1970s, a national system of free medical care for the aged was introduced, and there was a massive increase in the pension benefits. When the 'bubble' burst, the national scheme of free care for the elderly was discontinued in 1983, and various other contractions were enforced. At the beginning of the twenty-first century, state-of-the-art biomedical technology is available in Japan, although brain death was legally recognized only in 1999, and the Japanese have shown considerable resistance toward organ transplantations in general.

Japan enjoys one of the lowest crime rates in the industrialized world. However, organized crime is a serious problem without any realistic solution in sight. The targets of organized crime are usually highly specific, without threatening the general public. However, periodically, Japan is shaken by outbursts of crime such as that perpetrated by the Aum Shinrikyō cult, which in 1995 spread poisonous gasses in a Tokyo underground station, causing 5000 deaths and injuries.

Conclusions

The critiques of 'totalizing' and 'essentializing' representations of culture/society/people have led the anthropology of Japan in several productive directions, foregrounding diversity, and multiple voices, whereas the awareness of the nonlocalized nature of culture/society/people has stimulated anthropologists to come to terms with various new ways of looking at what indeed is the 'anthropology of Japan.' These new perspectives place Japanese culture and society in the global historical flow and geopolitics, rather than treating them as a hermetically sealed entity.

Abstract

An overview of Sir Harold's life, work, awards, honors, and many achievements is presented. Emphasis is placed on his fundamental work in creating and applying an operational axiom system for probability theory that is helpful to scientists and applied workers in their efforts to learn from their data and experience and to create and use models to explain the past and predict, fundamental objectives of science. His reasonable degree of belief definition of probability is operational and permits probabilities to be associated with degrees of belief in alternative hypotheses and models. These degrees of belief can be updated logically by use of Bayes's Theorem to reflect information in new data and used to perform significance tests that Jeffreys developed which are very useful in choosing between or among alternative hypotheses and models. That his estimation, testing, prediction, and other techniques work well using nonexperimental data from geophysics and astronomy, as well as data generated from controlled experiments is of great interest to many, including many social scientists who work mainly with nonexperimental data.

Sir Harold Jeffreys, F. R. S. was born on 22 April 1891 in Fatfield, County Durham, England, and died on 18 March 1989 in Cambridge, England. He was educated at Armstrong College, Newcastle-upon-Tyne and at St. John's College, Cambridge University. After brilliant scholastic performance, he became a Fellow of St. John's College in 1914. From 1946 to 1958, he was Plumian Professor of Astronomy and Experimental Philosophy at Cambridge University. In 1925, he was elected a Fellow of the Royal Society, later became its Bakerian Lecturer and Royal Medalist and received the Copley Medal in 1960. He was knighted in 1953, President of the Royal Astronomical Society, 1955–57, and President of the International Association of Seismology and Physics of the Earth's Interior, 1957–60. In 1962, the Harold Jeffreys Lectureship was created by the Royal Astronomical Society and Jeffreys presented the inaugural lecture in 1963.

The obituary in *The Times* of London, 23 March 1989, noted that Jeffreys's 'famous treatise, *The Earth: Its Origin, History and Physical Constitution*, which with re-editing and improvements, went through seven editions between 1924, when it first appeared, and 1976, did perhaps more than any other book to make the geophysics of the solid earth a coherent study. His researches in seismology, in particular, established his reputation as one of the leading authorities on that subject.'

His early research was centered on astronomical and meteorological dynamics. An accomplished mathematician, he wrote two monographs, entitled *Cartesian Tensorsand Operational Methods in Mathematical Physics*. He and his wife, Dr. Bertha Jeffreys, a very able mathematician, wrote *Methods of Mathematical Physics*, which was published in several editions by Cambridge University Press and became a highly respected and widely cited classic. In a review of the work in *Nature*, it is stated that 'The authors distinguished for their knowledge of mathematical physics and cosmogony, and by their researches in these fields, possess also a remarkably comprehensive and deep understanding of pure mathematics. Their purpose has been to synthesize the mathematical knowledge for the service of physics ... The work is a benefaction to the cause of progress in natural philosophy.'

The Collected Papers of Sir Harold Jeffreys on Geophysics and Other Sciences was published by Gordon and Breach, London, in six volumes. Volume 6 is entitled, *Mathematics, Probability and Miscellaneous Other Sciences*. Work reported in this volume and in his books, *Scientific Inference* (1931 and later editions) and *Theory of Probability* (1939 and later editions) reflected Jeffreys's concerns with the foundations of science and, in particular, scientific inductive procedures. His book, *Theory of Probability* presents an axiom system for inductive inference applicable in all the sciences and operational procedures for description, measurement, modeling, data analysis, estimation, testing, and prediction. Many applications of these procedures to important statistical problems encountered in many sciences are provided in his books and papers.

Since he began research on probability theory after World War I in a series of papers written jointly with Dr. Dorothy Wrinch, his contributions have been of fundamental importance to the philosophy of science, scientific method, and theoretical and applied statistics. The general nature of this research has been stated in the preface of the second edition of *Scientific Inference* as follows: 'The general standpoint that scientific method can be understood if and only if a theory of epistemological probability is provided, remains unaltered. Consequently, I maintain that much that passes for theory of scientific method is either obscure, useless or actually misleading.'

In his book, *Theory of Probability*, Jeffreys presents a theory of epistemological probability, discusses its relevance for work in all areas of science, and applies it to solve many practical, important estimation, testing, prediction, and other statistical problems including those considered by R.A. Fisher, Joey Neyman, Karl Pearson, and others. Irving J. Good, an eminent statistician who reviewed Jeffreys's 1961 edition of *Theory of Probability* wrote that Jeffreys's book '... is of greater importance for the philosophy of science, and obviously of greater immediate practical importance, than nearly all the books on probability written by professional philosophers lumped together.'

As regards to Jeffreys's work on scientific method, he along with Pearson (1938) stressed the 'unity of science principle,' namely, that any area of study, for example, economics,

physics, psychology, etc., can be scientific if scientific methods are employed in analyzing data and reaching conclusions. Or as Pearson (1938, p. 16), cited by Jeffreys states, 'The unity of all science consists alone in its method, not in its material.' With respect to scientific method, Jeffreys, in his book *Theory of Probability*, provides an axiom system for probability theory which is useful to scientists in their efforts to learn from their data, explain past experience, and make predictions regarding as yet unobserved data, fundamental objectives of science, that are applicable in the natural, biological, and social sciences. He states that scientific induction involves observation and measurement and the production of generalizations or models to explain past data and predict new data, a view of induction that is fundamentally different from those of Mach and Popper. Further in induction, deduction plays a role but alone is inadequate for scientific work, mainly because deduction provides just three attitudes toward a proposition, namely, proof, disproof, or complete ignorance. As Hume and others have stressed, there is always the possibility of an exception to a scientific proposition. Thus, Jeffreys saw a need for statements less extreme than those of deductive logic, namely proof, disproof, or complete ignorance. His inductive logic provides such statements that involve reasonable degrees of belief in scientific propositions.

Jeffreys considers a probability to be a measure of the reasonable degree of confidence that an individual has in a proposition given the individual's available background information and data. This individualistic, subjective definition is compared to other definitions, including the axiomatic, long-run frequency, and hypothetical infinite population definitions in Chapter 7 of *The Theory of Probability*. He points out that the first definition is widely employed, for example, in the work of J. Neyman, the second is the Venn limit and strongly advocated by R. Mises, and the third is usually associated with R.A. Fisher although it had appeared earlier in statistical mechanics in the work of Gibbs and others. His criticisms of these concepts of probability are ingenious and devastating and have not been refuted in the literature, perhaps because they are irrefutable. In addition to specific detailed examples illustrating the inadequacies of these three definitions, Jeffreys comments, 'No probability has ever been assessed in practice, or ever will be, by counting an infinite number of trials or finding the limit of a ratio in an infinite series ... A definite value is got on them only by making a hypothesis about what the result would be. The proof even of the existence is impossible. On the limit definition, ... there might be no limit at all ... the necessary existence of the limit denies the possibility of complete randomness, which would permit the ratio in an infinite series to tend to no limit.'

After further detailed criticisms of the above three definitions of probability, he writes, 'The most serious drawback of these definitions, however, is the deliberate omission to give any meaning to the probability of a hypothesis' (1998, p. 377). Also, he remarks, '... in practice no statistician ever uses a frequency definition, but that all use the notion of degree of reasonable belief, usually without even noticing that they are using it and that by using it they are contradicting the principles they have laid down at the outset' (1998, p. 369). See also Jeffreys's (1998 pp. 30–3) discussion of the 'personalistic' or 'moral expectation' views of probability.

Having provided a definition of probability, Jeffreys's axiom system provides procedures for using such probabilities in a coherent way. That is, he provides basic analysis that yields the addition and product rules and other results, including Bayes's Theorem or the principle of inverse probability that Jeffreys states (1998, p. 28) was '... first given by Bayes (1763). It is the chief rule involved in the process of learning from experience.' It is invaluable in using data to revise our initial beliefs in propositions regarding the values of parameters, alternative hypotheses and models, future values of variables, etc. With this analysis, Jeffreys presents a logically consistent framework for learning from data to explain the past and to make predictions about future outcomes, primary objectives of science, as mentioned above. He demonstrates, through analyses of many applied problems using data, that his estimation, prediction, and testing procedures work well in practice and makes many comparisons with results provided by the maximum likelihood approach of Fisher and others, Neyman-Pearson testing procedures, Fisher's p-value approach to testing, etc.

Central in Jeffreys's work on statistical estimation, prediction, and testing problems is Bayes's Theorem. Whatever the estimation problem, use of Bayes's Theorem enables an investigator to combine his prior information regarding possible values of the parameters, represented by a 'prior density' with the likelihood function that incorporates the information in the data to obtain a 'posterior density' for the parameters that incorporates all the prior and sample information. That is, using Bayes's theorem, the posterior density is proportional to the prior density times the likelihood function with the factor of proportionality a numerical constant such that the integral of the posterior density over its range is equal to one. Thus for whatever problem, given the inputs, a prior density and a likelihood function, a posterior density for the parameters is available. This posterior density can be employed to compute the probability that a parameter's value lies between any two given values, say between 0.4 and 0.6, a solution to the famous inverse problem posed by Bayes. Optimal posterior point estimates for parameters are obtained easily from a given posterior density, say a posterior mean, median, or modal value that are optimal in terms of minimizing posterior expected loss *vis à vis* squared error, absolute error, and zero-one loss functions, respectively. Further, in large samples, Jeffreys (1998, p. 193) shows that under general conditions, the posterior density assumes a normal shape centered at the maximum likelihood estimate with a covariance matrix equal to the inverse of the estimated Fisher information matrix (1998, p. 193) and remarks that R.A. Fisher's maximum likelihood methods yields '... results which are indistinguishable from those given by the principle of inverse probability (in large samples), which supplies a justification for it' (1998, p. 194).

Since a suitable prior density is needed to utilize Bayes's Theorem and has been a bone of contention for many years, Jeffreys devoted considerable attention to the problem of formulating appropriate prior densities. In particular, he put forward a reproducible way of formulating invariant prior densities appropriate for use in situations in which an investigator is ignorant, or wishes to proceed as if he were ignorant, about the possible values of parameters. His famous recommendation

in such circumstances is to take the prior density for the parameter(s) proportional to the square root of the determinant of the Fisher information matrix (see pp. 179ff for material on invariant priors). Use of this 'ignorance' or 'diffuse' or 'noninformative' prior density provides invariant posterior probability statements for all continuous one-to-one transformations of the parameters, a remarkable and highly original solution to the choice of prior problem. Jeffreys derived many invariant priors and used them in analyses of applied problems. He is usually given credit for being a pioneer in considering and solving the problem of formulating invariant priors.

With respect to prediction, in general a probability density function for future, as yet unobserved, observations is formulated conditional on parameters with unknown values. If we have, for example, a proper prior or posterior density for the parameters, the product of it and the conditional predictive density can be formed and the parameters integrated out to yield an operational predictive density. It can be used to make predictive probability statements, for example, to compute the probability that a future, as yet unobserved, observation will lie between, for example, 3.4 and 4.7. Also, optimal point predictions can be derived for given predictive loss functions, for example, a mean for quadratic loss functions, etc. For more on uses of predictive densities for forecasting and control, see the general references cited above.

As regards to the evaluation of alternative models or hypotheses put forward to explain empirical phenomena, Jeffreys recommended workers to start with simple models and complicate if necessary. He and Dorothy Wrinch put forward the Simplicity Postulate, namely a statement that simpler models have higher probabilities of performing well. Jeffreys considered all possible models ordered with respect to degree of complexity and assigned probabilities to each, with simpler models receiving higher probabilities in an infinite sequence that is assumed to converge.

Within this broad modeling framework, on considering two alternative hypotheses, Jeffreys used Bayes's Theorem to derive an expression for the posterior odds on these two hypotheses that is equal to the prior odds on the two hypotheses times the Bayes's factor, the ratio of the predictive densities for the observations under the two alternative hypotheses. Jeffreys used posterior odds in his pathbreaking work on significance tests and compared his results for fundamental testing problems with those provided by use of Fisher's p-values and Neyman-Pearson testing procedures. Since Jeffreys's pioneering work on significance testing, many have employed and extended his methods to deal with a wide range of testing and model selection techniques, see, for example, the review paper by Kass and Raftery (1995). Given Jeffreys's brilliant formulation, interpretations, and uses of significance tests based on posterior odds, much improved methods for evaluating and/or combining hypotheses and models evolved and are now in widespread use.

Since Jeffreys's initial work in the 1920s many have come to appreciate his outstanding contributions to the philosophy and practice of science. It is noteworthy that he analyzed much nonexperimental astronomical and geophysical data. Yet his analysis of randomization in experimental design in his book *Theory of Probability* is extremely penetrating and valuable. In addition, he has made important contributions in the areas of distribution theory, asymptotic theory and expansions, robust estimation, invariance theory via differential geometry, information measures for distributions, mixture distributions, contingency tables, a key nonparametric problem, and in modifying the Pierre Simon Laplace Rule of Succession. And last, that Jeffreys's methods work not only in solving physical science problems but also in solving problems in biology, the social sciences, business, law, and other areas is noteworthy. Finally, while many orthodox statisticians were critical of Jeffreys's work years ago, it is the case that his approach and results are currently widely employed and valued.

Jewish Diaspora

Sergio DellaPergola, The A. Harman Institute of Contemporary Jewry, The Hebrew University of Jerusalem, Mount Scopus, Jerusalem, Israel

Abstract

Demography of world Jewry demonstrates the unique interplay that exists in the long run between the general concept of Jewish population and the normative concept of Jewish peoplehood. This article outlines the evolution of Jewish population worldwide between 1700 and 2013 covering population growth (besides the dramatic collapse caused by the Shoah), geographical distribution (between and within continents), life cycle events (births, deaths, and marriage), migrations (international and urbanization), conversions and assimilation, and the emerging age composition. The evolution of Jewish population globally reflects cultural, socioeconomic, and legal determinants and constraints experienced under minority and majority status.

Database and Conceptualization

The Jewish Diaspora is widely scattered and typically represents a small minority of the total population. The very definition of Jewishness may be subject to different interpretations. Therefore studying the demographic profile and trends of the Jews is subject to lack of uniformity of available sources. A singular overlap emerged all along Jewish history between the general concept of *Jewish population* and the normative concept of *Jewish peoplehood*. In the former sense, size and characteristics of Jewish population were significantly affected over time by the willingness, ability, and sometimes feasibility of individuals to identify as part of the given group. In the latter sense, the Jews' collective and shared belonging was often deeply affected by trends and events involving the demographic sphere, such as sudden quantitative decline because of major epidemics, massive murder, or enforced conversions; more rarely increase because of large-scale affiliation or high birthrates; or cultural–contextual change associated with large-scale migration movements.

Jewish demographic trends cannot be assessed without first addressing the empirical definition of *who is a Jew*. Figures reported below mostly relate to the concept of *core Jewish population*, i.e., *all those who, when asked, identify themselves as Jews; or, if the respondent is a different person in the same household, are identified by him/her as Jews*. This is an intentionally comprehensive approach, reflecting both subjective feelings and community norms and bonds. Definitions are admittedly looser in the Diaspora than in Israel where personal status is subject to ruling by the Ministry of Internal Affairs. The *core Jewish population* broadly overlaps but does not necessarily coincide with the *halakha* (Rabbinic) definition of a Jew as someone who *is the child of a Jewish mother or converted by appropriate religious and legal procedure*. Inclusion in *core* Jewish population statistics does *not* depend on any measure of a person's Jewish commitment or behavior in terms of religiosity, beliefs, knowledge, community affiliation, or otherwise. The *core* Jewish population includes all those who converted to Judaism, or decided to join the Jewish group and declare themselves Jewish. It excludes those of Jewish descent who have formally adopted another religion, as well as other individuals who did not convert out but currently refuse to recognize their Jewishness (DellaPergola, 2013).

Concurrently, the concept of *enlarged Jewish population* includes the sum of (1) the *core* Jewish population, (2) all other persons, Jewish by birth or parentage who do *not* currently identify as Jews, and (3) all the respective *non-Jewish* household members (spouses, children, etc.). The *enlarged* Jewish population is by definition significantly larger than the *core* population. The *Law of Return* – Israel's distinctive legal framework for the eligibility and absorption of new immigrants – further extends its provisions to all current Jews, their Jewish or non-Jewish spouses, children, and grandchildren, and the respective spouses. As a result of its three-generation time perspective and extended family definition, the Law of Return applies to a much wider population than *core* and *enlarged* Jewish populations alike. The Law of Return, per se, does not affect a person's Jewish status. While it defines clear-cut normative rules for the attribution of certain rights and prerogatives, the initiative for being entitled to its provisions stems from the people's individual awareness or willingness to belong to the Jewish collective, or to have some Jewish ancestry. Since the second half of the twentieth century, cultural identities have tended to become an increasingly important factor in determining the boundaries, size, and demographic characteristics of Jewish population.

Two main interacting drivers crucially shaped Jewish population size and characteristics in the longer run: external forces out of the control of Jewish communities and mostly operating in the global and regional political sphere; and internal forces stemming from the peculiar culture and social structure of the Jewish collective itself (DellaPergola, 2002). A further significant role was played by the changing modes of interaction between Jewish minorities and the majority of society, under rules and constraints usually dictated by the latter. At least five more specific determinants deeply affected the different desirability, feasibility, and availability of socio-demographic events among Jews, their frequency compared to others, and trends over time at the community level:

- unique *traditional culture and community organization*, or the minority's religious and social norms relevant to individual

demographic and social events, as well as collective frameworks and institutions apt to implement or facilitate those norms;

- legal provisions or – more relevant to contemporary history – subjective perceptions concerning a minority's *dominance/dependence* status vis-à-vis the majority of society or other minorities within it;
- *social class stratification*, and the consequent inter- and intra-group differences in perceived interests and access to resources;
- available *knowledge* on the given socio-demographic process, whether acquired through formal education or other channels;
- *biological constraints* of genetic or other nature, in relation to inherited properties affecting exposure to health risks or chances for survival. In this respect, it is essential to stress the difference between contemporary understanding of the human genome, scientifically grounded and prejudice-free, and anti-Jewish racialist approaches of a previous generation.

Demographic trends also very much draw on nondemographic factors such as the general state of world and regional economies, global cultural change, the role of religion, available technology, and political and military affairs. The combination of these factors and their interactions with demography determined the size and characteristics of Jewish populations in specific locations – hence the broader Jewish profile globally.

Jewish Population Growth 1700–1939

Until the late seventeenth century, poor health among populations generally, and inferior access to civil rights among Jews particularly, rendered population growth slow and unstable. When these negative constraints began to weaken, thanks especially to improved nutrition and to early emancipatory steps, world Jewry started to grow. Compared to a rough estimate of 1.1 million Jews in 1700, an estimated total of 2.5 million was attained around 1800. While until the seventeenth century overall Jewish population growth had been slower than that of world population, during the eighteenth and nineteenth centuries, world Jewry increased at a comparatively faster pace. Jewish population reached 4¾ million in 1850, and between the 1880s and 1914 yearly growth rates of 1.6–1.8% were attained by Jews globally. In 1900, world Jewish population was estimated at 10.6 million, a fourfold increase over 1800, and in 1914 it reached 13.5 million. Close to World War I Jewish growth rates began to slow down, but the absolute increase in Jewish population continued to be substantial. By the eve of World War II, the Jewish population had reached a historical maximum of 16.5 million. The annual rate of growth diminished to about 0.8%, while the world's total grew from 1920 to 1940 by 1% annually. Whereas in the nineteenth century the relative growth of the Jews had largely exceeded that of the peoples of Europe, North America, and the less-developed regions, this was no longer true in the period between the two World Wars.

The demographic expansion just outlined was not evenly spread across the different regions of Jewish settlement in the Diaspora, but mostly affected Jewish communities in Eastern Europe (see Figure 1). Jewish population growth rates of over 2% a year prevailed in Eastern Europe during the last quarter of the nineteenth century, surpassing Europe's faster growth rates at that time (1.5–1.7% annually for England, Poland, and Russia between 1880 and 1910). The rapid emergence of Eastern Europe's communities as the largest centers of Jewish life can be appreciated by noting that whereas around 1650 they possibly consisted of less than 350 000 people, by 1900 – also counting Jewish emigrants from Eastern Europe to Western countries and their descendants – they had grown to an estimated 7.5 million.

Jewish population growth outside Eastern Europe was slower. A moderate pace of internal growth characterized most

Figure 1 Jewish population by major regions, 1700–2013.

Jewish communities in Western and Central Europe, where early low growth rates had been induced during the time of Jewish seclusion into ghettos. In North Africa and the Middle East, the slower development of societal modernization and higher death rates hindered population growth, and initial demographic expansion of Jewish communities did not take place until the last decades of the nineteenth century or the early decades of the twentieth century.

One major consequence of these regional gags was a radical change in the geographical distribution of the Jews. During the late Middle Ages, the Jewish presence had been more or less equally divided between the areas of influence of Christianity and the Islam. The demographic rise of the Jewish population in Eastern Europe during the eighteenth and nineteenth centuries gave it overwhelming predominance in the context of world Jewry. Around 1880 – before the beginning of major intercontinental migrations – Jews in Eastern Europe (including the Balkans) represented about 75% of the world total, up from an estimated 52% around 1700. Jewish communities in North Africa and Asia (including Palestine's small *yishuv* = Jewish community), while stagnating or slowly growing in absolute numbers, declined in relative share from about 35% of world Jewry in 1700 to 8% in 1880. Western and Central European Jewry kept their share of the total (14% in 1880 vs 13% in 1700), while new Jewish communities were emerging in America (3% of world Jewry in 1880 vs less than 1%, mostly in the Caribbean area, in 1700).

As a result of large-scale international migrations, many veteran Diaspora communities in Eastern and Central Europe, the Middle East, and North Africa shrank and became small and precarious, or virtually disappeared. Instead, two major demographic centers arose: the United States, where the final consolidation of the Jewish community occurred mainly in the period 1881–1924, and Palestine, which absorbed significant immigration between World Wars I and II but whose definitive demographic expansion followed the establishment of the state of Israel in 1948. Several secondary Jewish population centers emerged: in Western Europe, especially in France and England; in Canada, alongside the major Jewish Diaspora population in the United States; in South America, especially in Argentina; in South Africa and Australia. The more spectacular change in the geographical distribution of world Jewry was the increase in the number of Jews in America, from about 250 000 in 1880 to 1 175 000 in 1900 and nearly 3 500 000 in 1914, and from 3 to 11% and, by 1914, 25% of world Jewry. This rapid expansion of American Jewry reflected the migration of about 2 400 000 Jews between 1881 and 1914, of whom 2 150 000 went to the United States and Canada.

By converse, the relative share of Europe's Jews among total world Jewry continued to decline from about two-thirds in 1914 to 58% in 1939. On the other hand, the proportion of American Jews among world Jewry grew from about a quarter in 1914 to a third in 1939. But because of the U.S. immigration quotas which very strongly affected the Jews, after 1924 relative Jewish population growth became much greater in Latin America and South Africa, although the initial numbers were much smaller. On the other hand, there was a rise in the relative share of Jews in North Africa and, especially, in Asia. The main reasons were considerable Jewish migration to Palestine/Eretz Israel, to the Asian territories of the USSR, and also to Egypt, and an upward swing in the natural increase of the local Jewish population thanks to the eventual onset of mortality decline.

Jewish Population Trends 1939–2013

World Jewish population was estimated at 16.5 million in 1939, of which 9.5 million (58%) was in Europe, and was reduced to 11 million in 1945, of which 3.8 million (35%) was in Europe. The total loss of 5.7 million Jews in Europe reflects a somewhat higher number of direct and indirect victims of Shoah victims, minus some natural increase that occurred in countries not subject to enemy's persecution and annihilation. If the Shoah had not occurred, Jewish population was expected to grow by at least another 6 million by the end of the twentieth century (DellaPergola, 2006c). But instead, between 1939 and 1945, Jewish population diminished by about 400 000 in Western and Central Europe, and by about 5.3 million in Eastern Europe and the Balkans (including Turkey, with most of its Jewish population located on the European side of the Bosporus). Jewish population between 1939 and 1945 globally declined by 33%, in Europe by 60% – 30% in Western Europe and 65% in Eastern Europe.

The countries where Jews suffered the most during the war period were Poland (97%), followed by Greece (89%), Austria and Czechoslovakia (−88%), Yugoslavia (−84%), Germany and the Netherlands (−77%), the Baltic countries (−74%), Belgium (−66%), Byelorussia (−61%), Hungary (−55%), and Ukraine with Moldova (−51%). These figures point to the exceptionally tragic incidence of Shoah in countries all across occupied Europe's in Eastern Europe, the Balkans, Central and Western Europe. The Jewish population in several other European countries, including the major Soviet republic of Russia and other Western European countries suffered somewhat to quite lower losses. A few Western areas like the United Kingdom, the Scandinavian countries, the Iberian Peninsula, and Switzerland added some Jews through absorption of refugees or internal growth. Moreover in 1945 there remained a significant bulk of over 200 000 displaced persons, nearly double the amount on the eve of the war.

The process of reconstruction of European Jewry that started immediately after World War II brought about gradual normalization of the more acute cases of displacement, return to normal family life, and a temporary substantial increase in the low Jewish birthrate that had prevailed since the 1930s. Much broader Jewish population redistribution involved the emigration to Israel of many Shoah survivors and the massive transfer thereof large numbers of Jews from Islamic countries prompted by violence that accompanied Israel's war of Independence. Subsequently, Israel continued to constitute the main country of access for Jewish migrants from Eastern Europe – that in the meantime had mostly fallen under the control of the Soviet Union. In turn, with the advancement of decolonization especially in North Africa, large-scale Jewish migration impacted the geography of European Jewry. The net consequence during the years 1945–70 was a further reduction of European Jewry by nearly 600 000 (−15%), but while Western Europe gained on balance 168 000 (+18%), Eastern Europe lost 736 000 (−26%). The European country that

benefited the most was France, with a nearly threefold growth (Bensimon and DellaPergola, 1984), with moderate gains of 10–15% in the United Kingdom, Austria, Italy, and Spain. On the other hand Jewish population diminished in Eastern Europe by as much as −91% in Poland, −84% in Romania and Bulgaria, −67% in Czechoslovakia, −61% in Hungary, −42% in Yugoslavia, and −33% in Germany. The Soviet Republics in Europe were more stable when some of those displaced during the war resettled while emigration to the West and Israel was only at its incipient stages.

Still regarding Europe, the more recent period (1970–2013) was dominated by significant emigration from the Soviet Union after the June 1967 war, the collapse of the USSR, and the massive exodus from what now was the Former Soviet Union (FSU). The Jewish population in Europe diminished by 1.8 million (−56%), from over 3.2 million in 1970 to just above 1.4 million in 2013 (10% of world Jewry). Decline was about 100 000 in Western Europe (−7%) and over 1.7 million in Eastern Europe (−82%). Looking at individual countries, the most affected were Byelorussia and Ukraine with Moldova (−92%), Romania (−87%), the Baltics (−83%), Russia (−76%), Bulgaria (−71%), Poland (−64%), Turkey (−56%), Czechoslovakia (−54%), Yugoslavia (−46%), Hungary and Greece (−31%). Among Western countries, the United Kingdom and Ireland underwent a decline of −26%, and several other countries (France, Italy, Switzerland) lost around or more than 10%. The main beneficiary of population transfers was Germany whose Jewish population grew nearly fourfold, with smaller growth in Spain and Portugal, Austria, and Scandinavia.

Of the 11 million Jews left in the world in 1945, about 564 000 lived in Palestine; in May 1948, at Israel's independence, there were about 650 000. The state of Israel became the main outlet of Jewish international migration. After the initial inflow of 690 000 immigrants in 1948–51, hence nearly doubling the initial Jewish population, the intensity of immigration waves that reached the country tended to decline over time, until the major upsurge of 1990–91 when 376 000 immigrants mostly from the FSU arrived. Israel's Jewish population grew rapidly, reaching 1 million in 1949, 2 million in 1962, 3 million in 1976, 4 million in 1991, 5 million in 2001, and 6 million in 2013. Mass immigration from Europe, Asia, and Africa was the major determinant of growth until the early 1960s. In later years, with the reduction of Jewish international migration after the mass exodus of Soviet Jewry, natural increase became the predominant factor of Israel's Jewish population increase.

Table 1 summarizes the main changes in Jewish population size and distribution between 1948 and 2013, when the world's Jewish population was assessed at 13 855 000, of which 6 014 000 were in Israel (43% of world Jewry). The fast growth in Israel's population was matched by massive decline in the Middle East, North Africa, the FSU, and other countries in Eastern Europe. Significant decline occurred also in Latin America and South Africa. Oceania is the region out of Israel that experienced the fastest Jewish population growth, while North America experienced lesser relative growth but larger absolute population increase. Western Europe experienced initial growth followed by minor decline.

Reflecting continuing Jewish population increase in Israel and stagnation or continuing decline among Jewish communities in the rest of the world, over 90% of world Jewry lived in five countries in 2013, of which 82.6% in the two largest of Israel and the United States, and 98.7% lived in 22 countries with at least 15 000 Jews (Table 2). Excluding Israel from the count, over 90% of Diaspora Jews lived in seven countries, of which 69.2% in the United States alone and 97.8% lived in 21 countries. Besides the two major Jewish populations (Israel and the United States), comprising over 5 million persons, another seven countries each had more than 100 000 Jews each – three in Western Europe (France, the United Kingdom, and Germany), one in Eastern Europe (the Russian Federation), one in North America (Canada), one in South America (Argentina), and one in Oceania (Australia). The dominance of Western countries in global Jewish population distribution is a relatively recent phenomenon and reflects the West's relatively more hospitable socioeconomic and political circumstances vis-à-vis the Jewish presence. The growth, or at least

slower decrease, of Jewish population in the more developed Western countries is matched by a higher share of Jews in a country's total population. The share of Jews in a country's total population tends to be related to the country's level of development, with most Jews concentrated in large, highly developed, central metropolitan areas. In 2013, more than half of the world Jews lived in five metropolitan areas, in descending order: Tel Aviv, New York, Jerusalem, Haifa, and Los Angeles. By adding another 10 areas (South Florida, Be'er Sheva, San Francisco, Washington/Baltimore, Boston, Chicago, Paris, Philadelphia, London, and Toronto), 75% of the world Jewish population were covered.

Regarding core Jewish populations in 2013, the share of Jews out of the total population in Israel (including Jews in East Jerusalem, the West Bank, and the Golan Heights, but excluding Palestinians in the West Bank and Gaza) was 75.4%. If also including the Palestinians in Gaza and the West Bank, the extant Jewish majority shrank to 50.5% of total inhabitants. Israel obviously is a special case, but it has become also quite a developed country (sixteenth by the UN Index of Human Development (2013)). Elsewhere Jews represented 17.3 per 1000 of total population in the United States; 3.9 per 1000 on average in the other seven countries with over 100 000 Jews; 0.8 per 1000 on average in the other nine countries with over 18 000 Jews; and virtually nil in the remaining countries which comprise the overwhelming majority of world population. In 2013, 95 countries had at least 100 Jews, but only 17 had more than 25 000. In 29 countries out of the 95, there was at least one Jew per 1000 of total population. The relationship between Jewish population size and its share of a country's total population is summarized in Table 3.

Table 3 World Jewish population distribution, by number and proportion (per 1000 total population), 1 January 2013

Number of Jews in country	Jews per 1000 total population			
	Total	0.0–0.9	1.0–4.9	5.0+
Jewish population distribution

International Migration

Among the mechanisms of Jewish population change, international migration crucially shaped the geographical distribution of the Jewish Diaspora across history and especially since the second half of the nineteenth century. About 9.2 million Jews moved between continents or across different geo-cultural areas between 1880 and 2012 (see summary in Table 4). Most Jewish migrants came from Eastern Europe, North Africa, and the Middle East. Over the 133 years estimated here, 59% went to Western countries, primarily the United States, and 41% to Palestine/Israel.

The continuous wavelike pattern in Jewish international migration (see Figure 2) demonstrates recurrent crises affecting the position of Jewish communities in different parts of the world and the consequent need for prompt relocation, which in turn suggests dependency of the Jewish Diaspora on changing political, socioeconomic, and cultural circumstances in the respective countries. Some of the stimulating factors of large-scale emigration operated in recent years essentially like they did at the turn of the twentieth century in spite of the deep intervening sociopolitical changes across world society and Jewish communities alike.

Three major Jewish migration waves were related to: (1) the pre–World War I mass migration from Eastern Europe to North

Table 4 Estimated Jewish international migration, by major areas of origin and destination – absolute numbers and percent distribution, 1881–2012

America, peaking in fiscal years 1905–06 (154 000 Jews admitted), 1906–07 (149 000), and 1913–14 (138 000); (b) the massive transfer to Israel of displaced Shoah survivors and of sizable Middle Eastern and North African Jewish communities between 1948 (peaking with 239 000 in 1949) and 1951; and (c) the more recent exodus from the FSU (228 000 in 1990 and 195 000 in 1991). These major moments of crisis or postcrisis adaptation occurred at comparable intervals of about 40–45 years, much in response to major events in the global polity (pre–World War I and post–World War II adjustments, the end of the Soviet Union). While no mechanical or deterministic assumption is suggested about the alignment of global geo-political forces, economists and demographers have discussed the possible cyclical unfolding of economic change and its impact on national political systems (Kuznets, 1958). Specific consequences for Jewish ethno-religious or social groups tended to stimulate mass migration. In between the major migration waves, several other significant waves appear, also quite regularly spread over the time axis, although each wave had its specific determinants and geographical origins.

The volume of the main Jewish migration flows is summarized in **Table 4** according to a fourfold geographical typology: Eastern Europe; Muslim countries in Asia and Africa; Western countries including America and Western Europe; Palestine/Israel, under Ottoman rule until 1918, under British mandate until 1948, and since 1948 the state of Israel. Until 1918, Eastern Europe was the main sending region and the United States the main recipient. During the interwar period, Eastern Europe continued to be the main area of origin but migration was sparser and Palestine emerged as a major country of destination. Since 1948, Israel became the dominant country of destination, especially between 1948 and 1968 (69% of total migrants) when the plurality of Jewish migrants came from Muslim countries in Asia and Africa. Since 1969 Eastern Europe again became the supplier of the majority of Jewish migrants, and Israel received 59% of the world total. In the balance of migration flows between Western countries and Israel, the former ended up with a moderate net surplus.

Jewish migration to Israel, usually called by the value-oriented Hebrew term of *aliyah* (*ascent*) consistently followed a wavelike pattern (Bachi, 1977; see **Figure 3**). Historiography

Figure 2 International migration of Jews, 1880–2011 – 5-year moving averages. Source: adjusted from DellaPergola, S., 2009. International migration of Jews. In: Ben-Rafael, E., Sternberg, Y. (Eds.), Transnationalism: Diasporas and the Advent of a New (Dis)order. Brill, Leiden, Boston, pp. 213–236.

has numbered such migration waves serially, starting with the 'first' (1881–1903) through the 'fifth *aliyah*' (1932–38). Similar cyclical patterns actually prevailed throughout the nineteenth century, though with relatively small numbers of migrants, and clearly continued throughout and beyond Israel's first 50 years of independence. In absolute numbers, the greatest single wave occurred in 1948–51, followed by others of declining size until the major surge of the early 1990s. However, relative to a rapidly expanding receiving population, the highest and quite unique impact of immigration on the receiving society was recorded during the 'fourth *aliyah*' (283 immigrants per 1000 Jewish residents in 1925), followed by Israel's 'great *aliyah*' (236 per 1000 in 1948 and 26 per 1000 in 1949) and the 'fifth *aliyah*' (201 per 1000 in 1935). The major wave of 1990–91 only generated 50–60 per 1000 yearly increases to a much larger receiving Israeli population.

Jewish migration was stimulated by a combination of political, socioeconomic, and cultural factors. Negative circumstances in the countries of origin determined the observed wavelike patterns. The volume and direction of Jewish migration largely reflected policies in the countries of origin and destination. Against limiting quotas enforced by the United States and other countries in the period following World War I and until the end of World War II, Israel since 1948 offered Jews nearly unrestricted immigration, socioeconomic incentives, and citizenship rights. Consistently with a comparatively less amount of return migration, the demographic and socioeconomic characteristics of Jewish migrants were generally less selective than among total international migrants. Despite its heterogeneity and initial low status, migration led to the growth and development of contemporary Israeli society and of the major Jewish communities worldwide and stimulated Jewish social mobility (Metzer, 1998; Schmelz et al., 1991).

Assistance provided by Jewish international and Israeli agencies generally enhanced migration. Various bodies promoted, directed, supported, and subsidized Jewish migrants, such as the Jewish Colonization Association, the World Zionist Organization and Jewish Agency for Israel, the American Jewish Joint Distribution Committee, the Hebrew Immigrant Aid Society, and Nativ, the liaison bureau of Israel's Government in the FSU.

Throughout the major part of the twentieth century, the overwhelming majority of world Jewish population was located in countries with high emigration propensities, but emigration significantly emptied those reservoirs. With the recent predominance of a Jewish presence in developed and free countries with low emigration propensities, short of significant changes in the current global and regional circumstances, the volume of Jewish international migration was bound to decline.

Vital Statistics and Population Composition

The historical transition from high to low birthrates and death rates mostly happened earlier among Jews than among surrounding total populations. Jews in spite of their obviously lower social status were among the forerunners of demographic change in modern societies, along with other small minorities of European society like the aristocracy and members of the urban *bourgeoisie*. The peculiarities of the nineteenth-century Jewish demography (lower death rates coupled with lower birthrates) were noted by scientists and writers who were developing their theories about *human races*. But instead of correctly interpreting these differentials in the light of cultural, social, and economic differences at the community level, these differences were attributed to alleged genetic characteristics. The myth of a special and dangerous *Jewish race*, able to survive under any climate and prone to multiply much faster than other populations, would lead to a quest to limit or altogether delete the Jewish presence, with catastrophic consequences for the Jews (Schmelz, 1971; DellaPergola, 2006a).

Lower death rates reflected significant differences in the incidence of various causes of death among Jews and non-Jews

in the same countries. According to the nineteenth- to early twentieth-century data, Jews suffered comparatively less from smallpox, typhus, cholera, tuberculosis, venereal disease, and excessive use of alcohol. They were reportedly more affected by diabetes, respiratory diseases, genetically transmitted disabilities, and some types of mental illness. Early declines in infant mortality contributed to higher population growth but also induced earlier fertility reductions among the Jews.

During the nineteenth and early twentieth centuries, higher birthrates, inasmuch as they existed, reflected nearly universal marriage and comparatively high marital fertility levels. With no exception, however, Jews anticipated by many years the respective surrounding populations in adopting more stringent control over reproduction, through postponing marriage and more effective birth control, and sometimes also through applying Jewish restriction about sex relations. This occurred true in a variety of environments in Western, Central, and Eastern Europe, in North Africa, as well as in communities generated by intercontinental migration, such as in the United Kingdom, North and Latin America. Conversions and other passages to and from Jewry, on the other hand, generally caused net losses to the Jewish population – hence a significant factor of attrition in long-term Jewish population growth.

After World War II, a 'baby boom' occurred especially in the United States, followed by renewed decline in Jewish birth. Jewish populations in Europe reached a state of demographic stagnation and decline, with deaths consistently outnumbering births (Table 5). This negative gap was strikingly high in the FSU European republics. In the Russian Federation in 2000, there were only 600 recorded Jewish births compared to over 8200 recorded Jewish deaths – a net loss of 7600. Such striking deficit reflects extreme population aging (see below), in part the consequence of the intensive emigration of younger Jewish adults and nuclear families with the consequence that large numbers of elderly remained behind in the FSU. In the United States, Jewish vital statistics are not directly available. However Jewish population projections based on available age composition and cautious assumptions about the age-specific frequency of motherhood and deaths suggest that the core Jewish population generates annually about 50 000 births and 58 000 deaths. The likely deficit of about 8000 is being compensated by a positive Jewish immigration balance.

Israel is the only exception to these recessive demographic trends. Steady immigration produced a doubling of Israel's

[a]Not Jewish at time of marriage. Intermarriage estimates are national or regional estimates and ignore geographic variations within countries. Demographers refer to this intermarriage rate as the 'individual intermarriage rate.' Rates are for marriages in the past 5–10 years.
[b]Data quality rated as follows: 1: Recent and reliable data; 2: Partial or less recent data of sufficient quality; 3: Rather outdated or incomplete data; 4: Conjectural.
Source: Adjusted from DellaPergola, S., 2009b. Jewish out-marriage: a global perspective. In: Reinharz, S., DellaPergola, S. (Eds.), Jewish Intermarriage around the World (pp. 13–39). London, New Brunswick: Transaction.

Jewish population between 1970 and 2004, which was reinforced by a significant Jewish natural increase. In 1990, 73 900 Jewish births and 25 800 Jewish deaths produced a natural increase of 48 100. In 2012, 125 400 Jewish births and 35 900 Jewish deaths produced a net increase of 89 500. Demand for children continues to be strong among both the religious and the secular populations, rooted partly in Jewish communal identity and partly in a broader sense of economic optimism and life satisfaction, and resulting in significantly larger families in Israel than among Jews in other countries.

Low Jewish birthrates and population aging in the Diaspora are significantly impacted by high and continually increasing rates of intermarriage (Table 6). Overall, the rate of intermarriage has been increasing among Jews, but significant differences persist by country. In recent years, in the Russian Federation about 70% of recently married Jewish women and 80% of recently married Jewish men married non-Jews. In the United States, and in several medium-size European Jewish communities, the intermarriage rate was over 50%; in France and the United Kingdom, over 40%; in Canada and Australia, over 30%; and in South Africa and Venezuela, over 15%. Of the major Jewish communities, probably only Mexico had an intermarriage rate lower than 15%. The incidence of intermarriage significantly depends on the ethno-religious composition of parents: most of the total increase in intermarriage occurs among Jewish adults who are themselves the children of intermarried parents (Phillips, 2013). In Israel, the rate of intermarriage is less than 5%, low but not negligible, reflecting the growing number of non-Jews immigrated under the Law of Return, particularly from the FSU. Many of these intermarriages are performed in Cyprus (Dvorin, 2006). On average, based on 2010 global Jewish population distribution and recent intermarriage rates in different countries, about 29% of all recently married Jews worldwide, and 48% of all recently married Jews in the Diaspora, started a new family with a non-Jewish partner. Scattered data on cohabitation among young Jewish adults point to much higher rates of intermarried couples (DellaPergola, 2009b).

A further factor is the Jewish identity of the children of intermarriages. The percentage of the children of intermarriage raised as Jews during the early 1990s was about 20% in both the

[a]Countries sorted by date within type. The largest age-group in each population is in bold font.
[b]The median is the age in reference to which one-half of the population is younger and one-half is older. Some of the median ages were computed from more detailed age distributions than those shown here.
Adjusted from DellaPergola, S., 2012. World Jewish population 2012. In: Dashefsky, A., Sheskin, I. (Eds.), American Jewish Year Book. Springer, Dordrecht, pp. 213–283.

United States and the Russian Federation. In 2001, this percentage had increased in the United States to more than one-third, still far from the 50% that would be required so as not to contribute to a decrease in the number of Jews. Nonidentification with Judaism of many children of intermarriages, added to low fertility levels, produces an even lower 'effective Jewish birthrate.'

Age composition plays a crucial role in population change (Table 7). Data for 1975–2012 exemplify extreme variations in age composition following the transition from higher to lower birthrates and death rates. Jewish populations can be classified into five types, gradually moving from traditional to transitional, moderately aging, advanced aging, and terminal. Traditional Jewish populations, characterized by very high percentages of children, have virtually disappeared. Jews in Ethiopia before their mass immigration to Israel in 1991 were the last surviving example. The transitional type occurs as fertility is controlled and mortality declines. Such populations still feature relatively high percentages of children, an increasing share of adults, and a median age around 30 years or under. Israel in 2012 provided the only persisting example of a Jewish population where the percentages in each major age-group regularly decreased from the younger age-groups to the older age-groups. In moderately aging communities, the center of gravity moves to age 45–64, but children under 15 years of age are still more numerous than adults aging 65 and over. This type, with a median age about 35–40 years, predominated during the 1970s and through the 1990s in the United States, and still persisted in some communities in Central and South America like Mexico. More recently, Jewish communities in the United States – namely in New York, in Canada, in Western and Central European countries, in Central and South American countries like Argentina and Brazil, as well as in Australia and Turkey, joined the advanced aging type. In these populations, persons aged 65 and over outnumber children under the age of 15 years, and median ages mostly range between 40 and 45 but also tend to approach 50. The terminal age composition pattern is typical of the Russian Federation, other FSU republics, Germany, and several other Eastern European countries. It comprises percentages of elders that are double or more the percentage of children, with a median age of 50 or higher, eventually tending toward 60 years and over. Such populations are bound to continuous decline.

Job Analysis and Work Roles, Psychology of

Heiner Dunckel, International Institute of Management, University of Flensburg, Flensburg, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Job analysis is essential for understanding and changing working conditions and the workers themselves. Analyzing jobs is a crucial element in (psychological) work analysis because jobs and the tasks constituting them are the basic (design) units of an organization and the key interface between human beings and organization. This article briefly outlines job analysis methods and techniques, distinguishing them according to the criteria: unit of analysis, intended applications, theoretical foundation, method users and methods of data collection, methodological standards, and results. Emphasis is given – particularly in view of practical requirements – to the need for methods and techniques to be scientifically proven in terms of their reliability and validity. Finally, the future importance of job analysis and the necessary further developments are discussed.

Introduction

Job and work analysis is essential if we are to describe, understand, and change the way people work and their work environment. It is important because it is the basis for the solution of different human resource problems (Brannick et al., 2007). Job and work analysis also plays an important role in the European Union, as the European Framework Directive 89/391/EEC issued in 1989 legally commits every employer to conduct regular measures to encourage improvements with regard to the safety and health of workers at their workplaces. Generally speaking: If we wish to solve work-related problems, work analysis is not normally a matter of choice; we are either obliged to perform it explicitly or at least base our decisions on implicit work analysis information.

Job analysis is part of work analysis. It is necessary (see also Ghorpade, 1988) because

- jobs and their constituent tasks are the basic (design) elements of an organization, forming the basis for the constitution of workgroups, departments, and other larger divisions;
- jobs are consciously designed and changed by people (e.g., industrial engineers) who do not normally perform them;
- modern organizations are constantly changing (job analysis allows a continuous adjustment of job-related requirements to changing organizational goals).

There is a large number of jobs (e.g., in the production, office/administration, and service sectors) and elements of the work situation (e.g., organizational structures, agreements on working hours, work objects, and means of work), and a wide variety of ways in which job-related information can be used, that practically preclude the possibility of adopting a universal approach or analysis method here. Accordingly, there is no one job analysis method, but rather a number of systems, techniques, and methods that can be used to analyze jobs (Dunckel, 1999; Gael, 1988).

Nor are there any universally valid definitions, terms such as job, position, task, and element being used differently in different countries and approaches. This fact should be taken into account by the reader, for this article, too, uses terms in a way that would certainly not be endorsed by all job analysts.

Job analysis is the systematic, empirically oriented, problem-based collection of information on the interaction between humans and the work tasks and conditions that constitute a job or are connected with it "… by dividing it [the job] into smaller units, where the process results in one or more written products with the goal of describing what is done in the job or what capabilities are needed to effectively perform the job" (Brannick et al., 2007: p. 8).

Depending on the respective problem or goal (e.g., organizational planning and design, human resource management), different approaches and different techniques and methods are normally required (Dunckel, 1999; Gael, 1988; Ghorpade, 1988). A distinction should be drawn between job analysis and job evaluation: job evaluation in the narrower sense aims to determine compensation levels for a job (Landy, 1993); in a broader sense, job evaluation is also the evaluation of jobs according to given criteria, e.g., the extent to which jobs are conducive to health or personality development.

Jobs are composed of tasks, i.e., the same jobs are characterized by largely identical tasks. Task analysis is therefore a key element in job analysis (Dunckel and Resch, 2010; Landy, 1993). Task is generally taken to mean the purpose of a work system or the goal to be achieved under given conditions. Tasks specify goals to be attained by the worker, taking into account different overall conditions. Elements of jobs are therefore defined as work tasks if they relate in each case to different goals (more detailed treatment in Oesterreich and Volpert, 1987; Ghorpade, 1988). Tasks are the points in a job at which the organization meets concrete individuals and makes concrete demands on the activities of these individuals. The task is thus the 'interface' between the organization and the individual and an essential element in psychological job analysis.

Psychological job analysis systematically captures and evaluates information on a working individual's activity. Here, it is concerned not only with the externally visible activity and the conditions surrounding it, but also with the psychological processes (e.g., thinking, motivation) and structures (e.g., memory) determining and regulating this activity. Psychological job analysis thus focuses on the concrete work activity as a psychologically regulated activity – i.e., the activity of a working individual.

Unlike 'classical' work studies or technical (job) analyses, psychological job analysis is inconceivable without the involvement of the concrete working individual concerned. Supplying the affected workers with comprehensive information on the aims and objectives of an analysis, taking into account the fears and anxieties caused by it, and providing feedback to the workers on the results are (or should be) essential elements of any psychological job analysis.

Classification Criteria

Job analysis methods and techniques can be distinguished on the basis of various criteria (also McCormick, 1976): unit of analysis, intended applications, theoretical foundation, method users and methods of data collection, methodological standards, and results.

Unit of Analysis

The job analysis unit is the job itself and the tasks that comprise it. For this reason, many job analysis systems relate directly to the tasks and the immediate work conditions. More comprehensive job analysis systems (Dunckel, 1999; Gael, 1988) take into account the fact that essential features (e.g., potential for defining goals self-reliantly) and results of the tasks only become comprehensible if the overall organizational conditions and the knowledge, skills, and attitudes of the workers are taken into consideration. They therefore extend the analysis to include both the organizational conditions (e.g., degree of responsibility, codetermination potential, values and norms, leadership climate) and the working individuals with their respective knowledge, skills, and attitudes.

Methods can be classified, based on widely accepted criteria, according to whether they are more job/task-oriented or worker/person-oriented (Brannick et al., 2007). Job-oriented analysis is concerned with analyzing tasks, job conditions, or job features, without regard for the concrete individuals involved and their different knowledge, skills, abilities, and attitudes. Person-oriented analysis, on the other hand, is centered on the person and specifically concerned with differences among individual workers in the perception, interpretation, and performance of the job. Typical job-oriented approaches are: functional job analysis, task inventories, health services mobility approach (Gael, 1988; Ghorpade, 1988); typical person-oriented approaches are: position analysis questionnaire, critical incident technique, ability requirement scales, cognitive task analysis (Gael, 1988; Ghorpade, 1988).

The distinction between job-oriented and person-oriented analysis is of conceptual and practical significance. In stress research, for example, it is conceptually important to begin by determining stress factors independently of the person involved (and their individual perceptions and coping behavior) in a job-oriented manner, then going on to examine how objectively identical stress factors are differently perceived and dealt with by different individuals and how they affect different people. However, the (person-oriented) analysis of these interindividual differences means first determining objective stress factors because we are concerned here with interindividual differences in relation to objectively identical stress factors. This distinction is of practical significance when planning future workplaces for which there are not yet any workers. Here, the job-oriented approach is the only way of obtaining job analysis information.

Intended Applications

Techniques and methods have been and are being developed for different goals and potential applications. Job analysis literature contains numerous different lists of goals and proposed applications for job analysis information (Ash, 1988; Lees and Cordery, 2000). Basically speaking, two complexes of goals can be distinguished: work/job and organization design, and personnel development. More concrete aims of job analyses are, for instance, comparing work activities, changing and planning the work situation and organization, determining skill requirements and factors defining aptitude requirements, technology assessment, maintenance of industrial health and safety standards, and job evaluation.

Job analysis methods and techniques play an important part in human resources management and personnel selection (Algera and Greuter, 1998; Brannick et al., 2007). They are used to determine more precisely the requirements a person must meet to perform his or her work tasks. These requirements may be specified as tasks to be accomplished, behavioral requirements (e.g., required behavior or behavioral repertoire), eligibility requirements (e.g., knowledge and skills), or trait requirements (e.g., abilities and interests). For each of these requirement types, there are a number of techniques available (Gael, 1988).

If the results of such analyses are combined, job analysis can also be used to describe (work) roles as defined by Katz and Kahn (1978) (see also Dierdorff and Morgeson, 2007). According to these authors, roles are standardized behavior patterns demanded of all persons involved in a given functional relationship. Here, job analysis can also help to identify when and on what conditions role expectations (of the different organization members with respect to individual workplace occupants) can lead to conflicts and job stress.

The intended applications of job analysis are not necessarily independent of one another. If, for example, the goal is to change the work organization, it will often be necessary to analyze both the technological implications and the consequences for the workers involved.

Besides the application purpose, the application area also plays an important role. Job analysis techniques and methods consider different levels and units of an organization. A distinction must be made between

- sectors (e.g., industrial, administrative, service);
- levels of an organization (e.g., enterprise as a whole, business division, department, workplace group, workplace, work task);
- professional groups (e.g., executives, specialized professional groups); and
- activity classes (e.g., assembly, control and monitoring activities, administrative activities, service activities).

Depending on the specific concern, the emphasis will be on different information. Job analysis, too, faces the problem of breadth versus depth. The more detailed the information, the

more limited the application purpose. It may therefore be a good idea to proceed in several steps, starting with rough analyses to determine the key analysis areas, which are then analyzed in greater detail.

Theoretical Foundation

The theoretical foundation largely determines which information is captured at which level or with which analysis unit.

Work studies as defined by Taylor or Gilbreth (see Ghorpade, 1988) are based on an additive *movement* (or motion) model. Techniques working on this basis thus attempt to define elementary movement units (e.g., grasping with the hand), combining these additively in order to then determine, say, the standard time required to perform the work.

Approaches rooted in behaviorism also attempt to identify elementary units (of behavior) (e.g., processing materials, recognizing optical differences). Their units are bigger and hence they are therefore not movement-oriented but *behavior*-oriented.

These approaches, however, fail to take into account the fact that movements merge to form 'wholes,' are integrated in complex webs of activity and the regulating mental processes and representations, and are codetermined by these. This is why many developments, especially in Germany, are based on the '*action regulation* theory' (Frese and Sabini, 1985; Oesterreich and Volpert, 1987), thus giving priority to questions relating to the psychological regulation of action, the level of psychological regulation, the completeness of actions, the degrees of freedom (Hacker, 1998), or the scope for action or decision. The guiding idea here is that of humane work, i.e., work geared to human strengths and enabling individual workers to perform their job under permanently tolerable conditions, without impairment of their well-being and in a manner conducive to their personal development.

In the emphasis they place on characteristics such as scope for action, variability, identity, and importance of the task, action theory approaches are in keeping with the traditions of industrial sociology, e.g., the work of Turner and Lawrence (1965) and the work of Hackman and Oldham (1975) that build on this. Since the latter approaches are specifically concerned with questions relating to the 'motivation potential of work,' they can also be classified as oriented to *motivation theory* (*see* Work Motivation).

Besides drawing on approaches based on behavior, action, and motivation theory, job analysis systems also have recourse to concepts of stress theory (*see* Workplace Stress), ergonomics, and human engineering (*see* Human Factors and Ergonomics); in addition, worker-oriented approaches draw on concepts of personality theory.

Method Users

The main users of job analysis methods are the workers themselves, first-level supervisors, higher-level supervisors, job analysts, technical experts and other company experts, but also works and staff councils.

Whether and to what extent a method can be used depend, among other things, on the application requirements that must be met by the users. Important factors here, besides formal qualifications, are the amount of experience the users need in analysis techniques, whether they can teach themselves how to use such techniques or whether special training is required.

Methods of Data Collection

There are also fundamental differences between techniques in terms of the data collection methods used, for example:

- interview methods (e.g., individual and group interviews, technical conferences with experts, more or less structured questionnaires and checklists);
- observational methods (e.g., direct and indirect observation, continuous observation, work sampling);
- analyses of company data (e.g., working hours lost, accident statistics, workplace descriptions);
- analyses of documents (e.g., file analyses, form analyses); and
- work activities performed by job analysts.

Each of the methods has its advantages and disadvantages. It is therefore a good idea to combine several methods (Brannick et al., 2007; Gael, 1988). These advantages and disadvantages can be highlighted by comparing interview and observation methods.

Interview Methods

It is a good idea to interview workers, for they are the ones who know their own work activities best. Furthermore, such interviews are indispensable when the workers' subjective assessment of the work is needed or psychological processes are to be evaluated because these can only be accessed directly by introspection. In addition, interviews, especially questionnaires, are frequently the method of choice because they are relatively easy to develop and use. Interview methods are the most frequently used job analysis technique.

This should not, however, obstruct our view to the fact that interview methods have a number of weaknesses. Some typical problems are:

- comprehension problems of workers who are not so accustomed to dealing with the written language (e.g., in the case of questionnaires);
- the ambiguity of everyday language;
- difficulties in translating scientific terms into everyday language; and
- the problem of putting into words many aspects of psychological regulation processes (Hacker, 1998).

Observation Methods

Observation methods are generally used in cases where it is important to avoid the sort of errors that can occur in interview methods or 'bias' as a result of evaluation and interpretation processes on the part of the workers, or when, in future workplace design, no workers are yet available for the planned jobs.

Observation methods are often seen as a way of getting around the problems inherent in interview methods and obtaining 'more objective' data. In reality, they are subject to the same sort of problems as interview methods, in some cases giving rise to additional problems:

- The quality of job observations deteriorates for complex work activities.

- Certain temporally dynamic aspects of the work activity (e.g., pressure of time) are harder to observe.
- Infrequent events, which are nevertheless of significance for the job, (e.g., starting and stopping machines, annual accounts) are often not included.
- Observers, too, are subject to evaluation, interpretation, and 'biasing' processes. For instance, observers tend to rate workplaces as uniformly good or bad.

These typical advantages and disadvantages mean that proper job analysis involves considering precisely the methods which are suitable. This also means that users must be aware of the problems inherent in these methods, carrying out, where necessary, appropriate training measures to reduce them.

It is also a good idea – whenever this is feasible – to combine different methods, e.g., questionnaires, interview, and observation methods. For this reason, many techniques also include the *observational interview* as a proven data collection method, based on structured observation of the work processes and related interviews with the workers involved at their workplace.

This is also reasonable and required from a methodological point of view as a number of surveys show that data provided by incumbents have a significantly lesser reliability than data collected by analysts and experts (Dierdorff and Wilson, 2003; Voskuijl and Sliedregt, 2002; see also Dunckel and Resch, 2010).

Methodological Standards

Job analysis methods differ, among other things, in their degree of standardization – ranging from nonstandardized 'free' descriptions to semistandardized interviews to observations and interviews following exactly prescribed rules. They differ in the amount of time they take (from 30 min to several hours), their psychometric quality, the number of dimensions captured, etc. Which method to choose cannot be decided in a general manner; this depends largely on the intended application and on available knowledge and theory building with respect to the problems under investigation.

Scientifically based methods should be reliable and valid:

- The *reliability* of a method shows whether and to what extent a method can be used to obtain 'stable,' 'reliable,' or 'replicable' results. Ideally, repeated measurements of the same object should show as little deviation as possible (Oesterreich and Bortz, 1994).
- The *validity* of a method indicates the extent to which it actually measures what it is supposed to measure.

Examining these quality criteria is not only of scientific interest, but also of utmost practical importance. If the results of the analysis are to have practical consequences, e.g., for job design, decision makers must be able to depend on the fact that the results are reliable and valid.

Results

Job analysis methods provide quantitative and qualitative results. Qualitative results are mostly verbal, narrative descriptions of the job or the tasks; quantitative results are presented in numerical – and in some cases graphical – form. Complex methods generally present results in both qualitative and quantitative forms.

Outlook

Job analysis will continue to constitute a major basis for organization and personnel development also in the future. Given the numerous potential applications, there will be no one universal method covering all application purposes, even though the latest techniques allow more effective forms of information analysis and evaluation.

Job analysis methods were developed principally for the industrial and administrative sectors. They exhibit shortcomings, for example, when analyzing activities in the service sector, domestic and family work, and the self-employed sector. Furthermore, job analysis, too, will be obliged to respond to changes in the working world. New forms of work, e.g., jobs in virtual and networked organizations, teamwork within virtual structures, telecommuting and electronic business, dynamic and complex jobs with vague boundaries, also present new challenges for job analysis techniques and methods (Brannick et al., 2007; *see* Teamwork and Team Performance Measurement).

In addition, in the area of human resources management, job analysis is still needed (Ash, 1988) to help reduce gender discrimination with respect to pay by showing that the still existing differences in income between men and women on the same jobs cannot normally be justified by differing job requirements and conditions.

Abstract

Job evaluation is a method that is used to produce a hierarchy of jobs in an organization as the basis for determining relative pay levels. It seeks to measure the relative value of jobs, not that of the job holders. The main aim of job evaluation is to provide an acceptable rationale for determining the pay of existing hierarchies of jobs and for slotting in new ones. It may be implemented unilaterally by management or with varying degrees of participation by the workforce.

Job evaluation is a method that is used to produce a hierarchy of jobs in an organization as the basis for determining relative pay levels. It seeks to measure the relative value of jobs, not that of the job holders. The main aim of job evaluation is to provide an acceptable rationale for determining the pay of existing hierarchies of jobs and for slotting in new ones. It may be implemented unilaterally by management or with varying degrees of participation by the workforce. Acceptability, consensus, and the maintenance of traditional hierarchical structures are normally the goal of such schemes. Job evaluation schemes do not directly determine rates of pay. They are concerned with relationships, not absolutes. The rate for the job or the salary for a job grade is influenced by a number of factors outside the scope of most schemes. Normally pay is linked to external market rates, the relative bargaining strengths of the negotiating bodies, and traditional patterns of pay differentials between jobs. In recent years equal pay legislation has exposed job evaluation to sometimes rigorous analysis in the courtroom. Out of this are emerging principles which seek to ensure that job evaluation schemes are constructed and implemented transparently and without obvious bias (Acker, 2006).

Job evaluation is a method used to produce a hierarchy of jobs in an organization as the basis for determining relative pay levels. It seeks to measure the relative value of jobs, not that of the jobholders. Ideally, the performance of the individual should not enter into job evaluation although, in practice, it may be difficult to dissociate individuals from their jobs. Job evaluation is based on the assumption that components of work can be isolated and that these can be decomposed into elements considered worthy of remuneration.

The main aim of job evaluation is to provide an acceptable rationale for determining the pay of existing hierarchies of jobs and for slotting in new ones. It may be implemented unilaterally or with varying degrees of participation by the workforce. Acceptability, consensus, and the maintenance of traditional hierarchical structures are normally the goals of such schemes.

Job evaluation schemes do not directly determine rates of pay. The rate for the job or the salary market for a job grade is influenced by a number of factors outside the scope of most schemes. Often, the pay determinants and indeed hierarchies are linked to external market pay rates, the relative bargaining strengths of the negotiating bodies, and traditional patterns of pay differentials between jobs. Job evaluation is concerned with relationships, not absolutes.

The Rise of Job Evaluation

Job evaluation grew up in the first half of the twentieth century, in an era of large, bureaucratic organizations and increasing unionization. There was a shift toward more 'rational' and 'scientific' methods of determining pay differentials (Ruona and Gibson, 2004). A major concern was to justify pay levels since many industrial disputes were concerned with wages. Collective bargaining, unilateral wage determination, or individual negotiations were seen as unsystematic compared to job evaluation. The rise of mass production and sometimes-militant industrial unionism was also important. As a result of new production methods introduced at the end of the 1930s and during World War Two, the number of varied yet unskilled occupations increased sharply. The clear line between mass production and traditional craft jobs had become blurred. Pay on the basis of job content, not personal attributes, complemented this system of industrial relations.

Main Emphases in Job Evaluation Research

For many years the main interest in job evaluation has come from scholars in the fields of industrial relations, labor economics, and industrial psychology.

During World War II some academic economists had been members of, or attached to, the US National War Labor Board, a body which encouraged the use of job evaluation. Subsequently, some of these scholars, notably Clark Kerr, wrote about the industrial relations aspects of the subject (Kerr and Fisher, 1977). One of his conclusions was that the design of a scheme is of less practical importance than the context into which it is introduced and the way in which it is administered. Harold Northrup, another scholar with links to National War Labor Board, concluded that job evaluation was used by management 'partly to deter or prevent unionization, partly to rationalize its wage scales prior to unionization … and partly to stabilize the wage structure and eliminate continuous bargaining over particular rates after unionization.' (quoted in Hutner, 1986: p. 25).

In the 1940s a very different strain of research was started by industrial psychologists interested in the design of rational, equitable pay systems and psychometric issues of reliability and validity. This early research generally concluded that trained individuals, familiar with the organization's jobs and given detailed instructions on how to analyze them, could reach similar conclusions on overall job worth (see, for example, Ash, 1947). Interest in sex discrimination in pay systems stimulated further research on the validity of different job evaluation methods in the 1980s. This produced results which were much less clear (Arvey, 1986). Madigan (1985) concluded that, while the reliability of various methods tested was in the range from .70 to .90, the accuracy with which the predicted pay grade matched the actual grade was much lower.

The validity of job evaluation has been investigated by looking at the results of different methods, using predictive validity procedures, factor analysis techniques, and testing for potential sources of bias. Results have been contradictory, since some researchers have concluded that the results will be similar whatever the method used (for example, Robinson et al., 1974), whereas others have found significant differences (see Madigan and Hoover, 1986). There is some consensus that the skills and knowledge dimension, present in nearly all methods, is an overriding predictor of job evaluation results (Rogers, 1946; Madigan, 1985). It has been argued that this means that job evaluation mainly measures abilities that a person brings to the job, rather than the job content (Rogers, 1946). Another research finding is that where the evaluators know the job title this significantly influences the results (Smith et al., 1989). A review of the psychological literature has proposed, unsurprisingly, that 'research models need to be expanded beyond focusing on the psychometric properties of job evaluation' (Gerhart and Milkovich, 1992).

Recent research has drawn upon organization theory to study how individual and group power may influence the outcomes of job evaluation. The coalition model of organizations suggests that negotiation, bargaining power, and politics are key determinants of decision behavior, particularly resource allocation decisions (Pfeffer and Salancik, 1974). Using this approach Welbourne and Trevor (2000) examined whether power in a university affected job evaluation outcomes. They concluded that both departmental and individual positional power helped predict the results. Departmental power predicted the number of job grade allocations and reallocations achieved and positional power predicted the probability of favorable reallocation decisions. Powerful departments were more likely to approach the Human Resources Department with marginally acceptable requests and indulge in more extensive negotiations about the appropriateness of job descriptions and the proposed grade. The school's dean was likely to intervene prior to an official submission, particularly for higher graded positions. Welbourne and Trevor conclude that a rational model of behavior to explain outcomes is inadequate and that job evaluation captures the dynamics of the job's environment as well as its worth. Writing over 60 years earlier Viteles was less measured, claiming that 'beneath the superficial orderliness of job evaluation techniques and findings, there is much that smacks of chaos' (Viteles, 1941: p. 165).

Equal Pay and Job Evaluation

In the 1960s equal pay legislation was introduced in many western economies. The concept of equal pay for equal work has been widened in many jurisdictions to include equal pay for work of equal value. In the European Union, where a dispute arises as to whether work is of equal value, a country is required to provide a process by which an assessment of value can be made. Such a process involves some form of comparison based on job evaluation or classification. Where job evaluation is used it must be shown not to discriminate against women. In some countries, particularly the US, equal pay for work of equal value, also known as comparable worth, has proved to be a highly contentious issue. Economists, labor lawyers, historians, and sociologists have joined the debates. The role of job evaluation in bringing about equal pay for work of equal value has been scrutinized and vigorously disputed.

Among economists there are many that dismiss the use of job evaluation as a remedy for pay discrimination against women. They believe that to attempt to compare the value of different jobs using job evaluation is like 'comparing apples with oranges.'

The power dimension in job evaluation has been made more transparent by historical analyses of the way in which job evaluation has been used to maintain traditional male differentials, reflecting the prevailing values or relative power in society. Job evaluation, despite its rhetoric of fairness, does not necessarily lead to pay equity for women. During World War Two a US National War Labor Board case by the United Electrical Workers against General Electric (GE) and Westinghouse sought equal pay for work of equal value (Milkman, 1987). The job evaluation system used for all GE jobs gave different pay rates for men and women. The company responded that these gender-based rate differentials were longstanding, accepted by the union during bargaining rounds, and in line with industry practices. They argued that to pay women more would put the firms at a competitive disadvantage and that the board should consider 'sociological factors,' including women's different social and economic roles. Although the board decided in the union's favor, the companies ignored the decision (Milkman, 1987: pp. 80–1). Although explicit references to male and female rates disappeared gendered concepts, such as the distinction between 'light' and 'heavy' work, became the basis for unequal pay.

Until recently most job evaluation schemes continued to incorporate the gender bias of the early twentieth century (Treiman and Hartmann, 1981). Common practices were: the separation of men and women into different job evaluation schemes; greater weight being given to the attributes of male-dominated occupations; and using different scales for men and women when converting job evaluated points to pay rates (Baker and True, 1947).

The Law and Job Evaluation

Equal pay legislation has exposed job evaluation to sometimes rigorous analysis in the courtroom. Out of this are emerging principles that seek to ensure that job evaluation schemes are constructed and implemented transparently and without obvious bias. A distinction accepted in the European Court is

between analytical and non-analytical methods. In analytical schemes jobs are broken down into their component elements for the purposes of comparison. In non-analytical schemes the relative worth of the jobs may be based on a whole job comparison. More formal methods, particularly analytical schemes, have been judged to be more transparent and less susceptible to bias. However, it has been accepted that no scheme can ever be fully objective since the whole process is based on a series of judgments made about the facts presented to the evaluators. These judgments reflect each evaluator's background, experience, and attitudes.

Future Directions

By the middle of the 1980s job evaluation was being used by about 75% of US firms (Beer et al., 1985). However, for the past two decades increased individualization of the employment relationship has been developing and unions in most western economies have been on the retreat. Employers have been exhorted to be more flexible and willing to consider fundamental changes in employment practices. Increasingly job evaluation has been portrayed as bureaucratic, inflexible, reinforcing hierarchy, and not in tune with the needs of the times. Lawler has argued that in a rapidly changing, highly competitive environment, particularly where companies depend on advanced technology and the knowledge of their employees, pay systems should emphasize growth, development, and performance (Lawler, 1986, 1994). He claims that this is inhibited by job evaluation, which depersonalizes individuals by equating them with a set of duties, rather than concentrating on who they are or what they can do.

These views have been influential and there has developed a greater emphasis on paying people for their skills, knowledge, and performance. However, job evaluation, after becoming less fashionable in the 1980s and early 1990s, is in many countries more popular than ever. One reason for this is that the case against job evaluation has been overstated. Many of the problems associated with it can be overcome by redesigning schemes to fit the needs and values of modern organizations. A second reason is that there exists a flourishing job evaluation consultancy industry which has been quick to respond to some of the criticisms by modifying existing schemes and introducing new ones which incorporate more emphasis on skills, knowledge, competency, and performance. Broadbanding has introduced fewer, wider pay bands, thereby reducing hierarchical levels and the need for constant reevaluations.

A further influence has been that in many countries organizations have introduced job evaluation in order to be seen to be responding to legislative demands for pay equity between men and women. Job evaluation, carried out analytically, transparently, and with the participation of those concerned, normally provides a defence against potentially very expensive legal action.

Job evaluation will continue to change, but is unlikely to disappear. Employees expect equitable treatment. Even in an age of flexibility and individualism, it remains the most reliable means of achieving a pay structure that is perceived as both rational and fair by employees and their managers (Sholihin and Pike, 2009).

Job Displacement Insurance

Donald O Parsons, George Washington University and IZA Bonn, Washington, DC, USA

Abstract

Earnings losses from permanent job separations are a serious threat to the financial security of long-tenured workers. Job displacement insurance is presumably designed to offset these losses, but evidence suggests that consumption smoothing among the long-tenured displaced workers is seriously incomplete, at least in lightly regulated labor markets. Unemployment and reemployment wage insurance could fully cover these losses, but are costly to provide. Severance pay has emerged as a supplemental, if much criticized, instrument. Moral hazard limitations on unemployment insurance (UI) generosity mean that severance pay functions as scheduled (partial) UI and scheduled wage insurance. Consumption smoothing over time through savings and borrowing is less efficient than ideal insurance, but may be preferred in second-best situations. Long-tenured separated workers are older on average, which introduces special problems, but also additional policy options, including early access to retirement accounts.

Introduction

Earnings form the bulk of worker wealth in industrial economies and job displacement is a serious financial threat. Job displacement losses vary with the individual, the structure and flexibility of the labor market, and the business cycle, but are typically large and quite persistent among long-tenured workers. Although the economic risk of 'job displacement from a long-tenured job' is a real one to all workers, the fraction that experiences the event is not large. (For his sample of displaced workers in their 50s in the US, Couch reports a 2-year job displacement rate of 4.7% (Couch, 1998: p. 10).) Many workers will never become long-tenured, and long-tenured workers may remain employed until disability or retirement ends their work lives. Structurally, the long-tenured displaced worker is likely to have held a job with relatively stable demand, punctuated by infrequent but sharp permanent contractions.

Events that involve a small probability of a large loss are ideally insurance events, not saving or borrowing events. Earnings losses are usefully decomposed for insurance purposes into (1) those incurred through spells of unemployment and (2) those incurred through reemployment wage (rate) losses. Reemployment wage losses are apparently costly to insure, perhaps for administrative reasons, while unemployment losses are difficult to insure fully because of incentive problems deriving from the greater leisure available to the unemployed. If the utility value of benefits and the unemployed leisure is higher than that of working, incentives to seek and accept job offers fail (search moral hazard). (The resulting distortions can be dramatic if unemployment insurance (UI) rules are poorly written (Riddell and Kuhn, 2010).) Other distortions, often labeled 'firing cost' effects, arise if the employer bears substantial expected separation costs.

Standard commercial insurance is rare for this risk, but employers, trade unions, and governments offer various consumption smoothing mechanisms. Each has its own limitations, and supply elements play an important role in the composite insurance that emerges to moderate these risks. (A detailed discussion of the job displacement insurance policy alternatives can be found in Parsons (2014a).) Employers can offer simple separation packages to displaced workers and have one distinct advantage – they can avoid job displacement altogether by maintaining the worker on the job in low-demand times (labor hoarding). (Excessive labor hoarding is the focus of its own literature, carrying the label firing costs.) Trade unions can negotiate guaranteed employment agreements or separation benefits and even provide benefits directly. However, employers and labor unions have one critical disadvantage, an inability to monitor worker activities following displacement, which is required for actual-loss-based unemployment and reemployment wage insurance. Governments can reasonably monitor reemployment, at least if labor markets are largely formal, but struggle with subtler information like the intensity of job search. As a consequence, most separation packages involve only partial UI. (Card et al. (2007) and Chetty (2008) raise provocative questions about the welfare implications of UI-induced increases in unemployment duration. UI effects may include income (liquidity) effects as well as the usual incentive effect that concern most policy designers.) Severance pay, fixed-sum payments at the time of separation, serves as both scheduled wage insurance and (partial) scheduled UI in this second-best world. (Scheduled benefits mean fixed benefits linked to expected, rather than actual, losses.)

The important function of severance pay as scheduled wage insurance is often neglected in theoretical studies. These studies fail to distinguish between temporary separations, which normally involve no wage rate losses, and permanent separations, which do. (A detailed review of job displacement loss studies is provided below.) For example, Azariadis (1975), Rosen (1985), and Blanchard and Tirole (2008) focus on contracting issues and simplify by ignoring the reemployment market, essentially treating unemployment as an absorbing state. Shavell and Weiss (1979) and Shimer and Werning (2008) consider the behavior of unemployed workers only, so the models are silent on prior wages and therefore wage loss. Flemming (1978), Hansen and Imrohoroglu (1992), Hopenhayn and Nicolini (1997), and Pissarides (2010) introduce a reemployment market in a contracting framework

but simplify by assuming that wages are the same for workers pre- and postlayoff, thus permitting them to focus on unemployment.

Governments are quite active in this insurance market, often mandating that firms provide severance pay and, less frequently, directly supplying unemployment insurance; a summary of these efforts is provided below. The success of these measures in smoothing consumption following job displacement of long-tenured workers is more problematic. Cochrane (1991), using a general consumption approach proposed by Mace (1991), screened the U.S. for specific adverse events and identified involuntary job loss and, to a lesser extent, long-term illnesses (greater than 100 days) as being especially poorly 'insured.' A number of consumption studies, surveyed below, confirm Cochrane's finding. At least in US-style economies (US, UK, and Canada), long-tenured displaced workers experience large average declines in consumption.

One demographic group is of special interest. Long-tenured displaced workers are disproportionately older and may be eligible for disability and retirement benefits, with consequences for labor force participation and consumption smoothing. The decline in health status and marketable skills that often comes with age, when combined with the private and public income support systems meant to ease the impact of these declines on consumption, makes these workers an especially attractive policy target. Like private firms, governments often reduce the aggregate workforce by encouraging 'early retirement,' especially when unemployment is high.

Job Displacement Losses

There are a variety of reasons for job separation, with quite different consequences for earnings. Layoffs (employer-initiated job separations without cause) are the main focus here and must be distinguished from quits (employee-initiated job separation), discharges (employer-initiated job separations with cause), and other separations, including most prominently retirement. (These are U.S. Bureau of Labor Statistics (BLS) definitions. Elsewhere, BLS layoffs are often called redundancies.) Quits (voluntary separations from the perspective of the worker) are often advantageous to the worker, while discharges for cause are not, but for obvious reasons employers are averse to subsidizing such separations. Retirement carries the expectation that the worker will leave the labor force and often involves employer, union, or government financial support independent of job displacement insurance. Within separation categories, distinctions are also important, including that between permanent and temporary layoffs. Permanent layoffs are synonymous with job displacements. Temporary layoffs, common in the United States and Canada, are layoffs expected to result in rehire, often after a known time period.

Job displacement losses are often substantial. Consider the recent experience of job displacements of long-tenured workers (3 or more years of tenure at displacement) in the United States, derived from the BLS's Displaced Workers Survey. Of the long-tenured displaced workers from 2009 to 2011, only 56% were employed in January 2012, with another 26.7% unemployed, and the remainder (17.4%) out of the labor force altogether (BLS, 2012). The fraction out of the labor force jumps dramatically among workers 55 years of age and older (**Figure 1(a)**: Panel A). Among displaced workers from full-time wage and salary jobs who were employed in January 2012, 26.6% suffered wage losses of 20% or more (**Figure 1(b)**: Panel B).

Economists have devoted considerable attention to the structure of these losses; a few key studies are summarized in **Table 1**. The paradigm study is that of Jacobson et al. (1993a), who used administrative data to capture important elements of the dynamics of job displacement loss. (Jacobson et al. (1993b), Fallick (1996), Kletzer (1998), and Kuhn (2002) provide surveys of the literature.) Long-tenured workers (6 years of tenure or more) suffered earnings losses that begin well before displacement, with a sharp earnings drop at displacement, followed by a lengthy, incomplete recovery. As they reported, "We find that high-tenured workers separating from distressed firms suffer long-term losses [6 years following displacement] averaging 25% per year." (Jacobson et al., 1993a: p. 685). (Losses are relative to a control group of retained workers.) Short-term earnings losses were much higher, 45% in the first quarter after displacement.

The Jacobson, LaLonde, and Sullivan data represent a single state with a large heavy-manufacturing sector (Pennsylvania) and may be atypical. Couch and Placzek (2010) replicated the Jacobson, LaLonde, and Sullivan study on administrative data for Connecticut in a more robust, service-oriented labor market and find that earnings losses are significantly lower. Couch and Placzek (2010: p. 587) reported earnings losses of 32–33% in the quarter after displacement and 13–15% 6 years later. The lower loss estimates are to be expected given the countercyclical property of job displacement earnings losses (Davis and Von Wachter, 2011). The basic time profile of earnings losses was quite stable.

Studies based on survey data provide additional details of this process, including the partition of earnings losses into unemployment losses and wage losses. Ruhm (1991), using the Panel Study of Income Dynamics (PSID), reported persistence earnings losses following job displacement, on the order of 14.7% 4 years after job loss. With the survey data, Ruhm was able to break down the profile of losses by source. The high unemployment experienced following job loss had largely (85%) dissipated 4 years later, but earnings losses linked to wage rate losses remained large, with reemployment wages 14–15% below preseparation earnings.

Stevens (1997), also using the PSID, provided details on the nature of this loss process – not only are the displaced workers often forced to accept entry-level wages but also the new job will almost, by definition, have no seniority rights, making workers vulnerable to additional spells of unemployment. She reported relative earnings losses among displaced workers with 3 or more years of tenure of 26% immediately following separation. Earnings losses of 11% remained 6 or more years after displacement, almost all wage (rate) losses (Stevens, 1997: p. 178).

The U.S. Job Displacement Surveys provide ample historical evidence of earnings losses (up to 3 years following displacement), both on average and by job tenure (Farber, 2004). Average losses among the displaced workers included

Figure 1 (a) Labor force status by age January 2012 displaced workers with 3 or more years tenure 2009–11. (b) Distribution of reemployment wage loss in January 2012 of long-tenured (full-time) workers displaced in 2009–11. LF, labor force. Bureau of Labor Statistics (U.S. Department of Labor), 2012. Worker Displacement: 2009–2011. BLS news release USDL-12-1719.

employment losses of 32%, while wage losses among the full-time to full-time reemployed average 8% (Farber, 2004: pp. 113, 115). Earnings losses varied widely across individuals, industries, and economic conditions. Indeed, many individuals report wage gains, especially in good times (Helwig, 2001).

Expected losses were systematically larger for long-tenured workers. Averaged over the first ten Displaced Worker Surveys (1982–84 through 1999–2001), losses among full-time workers who secure full-time reemployment were as follows: 3.3% among workers with 1–3 years of tenure (relative to those

Table 1 Job displacement losses among long-tenured workers

Study	*Data source*	*Sample restrictions*	*Short-term earnings loss*	*Long-term earnings loss*
Jacobson et al. (1993a)	Administrative data, Pennsylvania	Tenure 6+ years mass layoffs	45% (Q1)	25% ($t+6$)
Couch and Placzek (2010)	Administrative data, Connecticut	Tenure 6+ years mass layoffs	32–33% (Q1)	13–15% ($t+6$)
Ruhm (1991)	PSID	Plant closings, permanent layoff	17.5% ($t+1$)	14.7% ($t+4$)
Stevens (1997)	PSID	Tenure 3+ years plant closings, permanent layoff	26% ($t+1$)	11% (6+ years)
Farber (2004)	DWS	Slack work, plant closing, position/shift abolished	32.4% employment loss 7.8% wage loss, FT to FT reemployed (3 years or less)	NA

Figure 2 Earnings change of displaced workers by tenure full-time employment to full-time reemployment first ten Displaced Worker Surveys. Farber, Henry S., 2004. Job loss in the United States, 1981–2001 accounting for worker well-being. Research in Labor Economics 23, 69–117.

with less than 1 year), 9.6% among those with 4–10 years, 18.6% for those with 11–20 years, and 24.7% among those with more than 20 years of tenure. (Author's calculations from Farber (2004: Table 3, pp. 96–97.) These are partial effects, controlling for gender, race, age, and years since displacement, for workers 20 years and older.) Loss *differentials* by tenure appear quite stable over the business cycle (Figure 2).

Job Displacement Insurance across Economies

Job separation packages vary widely across economies (2009), but not without logic (Table 2). (Holzmann et al. (2012) provide a detailed empirical account of variations in the size and composition of separation packages worldwide.) The administrative convenience of severance pay – the government need only mandate that private employers provide the

Table 2 Job displacement insurance coverage worldwide (countries with populations exceeding 1 million in 2009)

	Countries
Only statutory severance	69 (46.3%)
Both statutory severance pay and UI/UA	61 (40.9%)
Only UI/UA	13 (8.7%)
With significant collectively bargained severance	12
With no significant collectively bargained severance	1
None	6 (4.0%)
Total	149

UI, unemployed insurance; UA, unemployed assistance.
Source: Author's calculation from amended Holzmann, Robert, Pouget, Yann, Weber, Michael, Vodopivec, Milan, 2012. Severance pay programs around the world: history, rationale, status, and reforms. In: Holzmann, Robert, Vodopivec, Milan (Eds.), Reforming Severance Pay: An International Perspective. World Bank, Washington, DC, Annex B.

instrument – makes it especially popular. (Severance pay has its own potential limitations, the firing cost problem, discussed in Insurance Design below. Parsons (2013) provides a recent review of severance pay theory and empirics.) In a sample of 149 countries with 1 million or more inhabitants, 130 (87%) had some form of mandated severance pay, including 27 that had both statutory severance and collectively bargained severance pay in a 'significant manner' (Holzmann et al., 2012: Annex B). (Author's calculation from Holzmann et al. (2012: Annex B).) Another 13 (9%) had only significant collective bargaining severance. (This group includes the US, where collective bargaining agreements do often include severance pay provisions (Pita, 1996), but where collective bargaining is limited. Voluntary plans are however prevalent (Bishow and Parsons, 2004).) Only six (4%) had neither.

UI is more difficult to provide, and, not surprisingly, much less common. Of the 130 countries in the sample with statutory severance pay, only 61 (47%) provided UI, while 69 did not. Another eight (6%) with statutory severance pay offered means-tested unemployment assistance. Of the 13 countries with only collectively bargained severance, 11 countries provided UI and another unemployment assistance. None of the six countries that had neither statutory nor collectively bargained severance (the Democratic Republic of the Congo, Iraq, Haiti, Lebanon, Gambia, and Timor-Leste) provided UI.

The various combinations of UI/assistance and mandated severance pay are not random, but are closely linked to country income and presumably government competencies. GDP per capita in the six countries that had neither mandated severance nor some form of UI was only $1999. Of the 69 countries that had only mandated severance pay and no UI, average GDP per capita was $5810. Of the 61 countries with both mandated severance and some form of unemployment benefit, the average GDP per capita (in 2009 U.S. dollars) was $14 418.

Insurance Adequacy

On average, displaced workers with long tenure suffer serious long-term earnings losses, which, in the absence of consumption smoothing instruments, will have adverse effects on household consumption. There are many such devices, private and public, and it is natural to ask how effective these efforts are at smoothing the consumption of displaced workers. A number of consumption studies of displaced workers provide evidence on that question. Unfortunately, these studies are limited to 'Anglo-Saxon' countries (the UK, Canada, and the US), which have broadly similar labor markets and social insurance systems. In all three countries, labor markets are relatively 'flexible,' UI replacement rates are moderate, and severance pay is modest. (Severance pay is voluntary in the U.S. and, if offered, typically provides 1–2 weeks pay per year of service. Canada mandates 1 week pay per year of service, the U.K approximately one half-week per year of service (Holzmann et al., 2012: Annex B).)

Assessment studies focus on the consumption, not the utility, effects of displacement, no doubt in the belief that wage changes upon reemployment will have only modest effects on work hours. The U.S. study by Cochrane (1991) flagged job displacement as an especially serious threat to consumption stability. "Households that experienced an involuntary job loss had consumption growth 24–27% points lower than households that did not …" (Cochrane, 1991: p. 969). Other studies, directly focused on the negative consumption effects of job displacement, confirmed that they are substantial. Stephens, for example, tracked out the impact of job loss ('plant closed/employer moved' and 'laid off/fired') on earnings and on consumption over time in the U.S. (PSID). He found a long-term decline (6 years after displacement) in the earnings of the household head of 21.9%, with a decline in family food consumption of half that amount, or 11% (Stephens, 2001: p. 33). Among older workers (age 50 to early 60s), the relative change (loss) in annual food consumption within 1 year of job loss was 15% (PSID)–17.5% (Health and Retirement Study (HRS)) (Stephens, 2004: p. 268) (**Table 3**).

Consumption studies using Canadian and U.K. data revealed similar regularities. Browning and Crossley (2008), using Canadian data, assess the impact on consumption of *permanently* displaced workers (plant closure and other mass layoffs). They reported consumption losses of about 6% relative to consumption growth for those laid off with known recall data. Losses were higher for workers with tenure greater than 10 years or age greater than 40 years (10%). Bloemen and Stancanelli (2005) estimated a model of food consumption growth (from prior to layoff to 3 months after) in the United Kingdom, and report a decline in consumption of 17%.

Researchers have also estimated the impact of variations in job displacement insurance, especially UI generosity, on consumption of the unemployed. Presumably, consumption will vary (positively) more closely with benefits the more critical the benefits are as consumption support when earnings drop. Browning and Crossley (2001), using the same Canadian data set discussed above, estimated the sensitivity of consumption to changes in the key unemployment benefit parameter, the replacement ratio. They reported almost no impact of UI generosity on consumption – an elasticity of 0.05 (a 10% decrease in the replacement rate will induce a half-a-percent decrease in consumption). (Gruber (1997) reported extremely large UI replacement rate effects on consumption in the U.S. (consumption elasticity with respect to UI benefits of 0.25 for the whole population), but this estimate is inconsistent with later estimates and should probably be treated as an aberration.) The effect was somewhat higher for vulnerable subgroups, 0.17, for example, for sole breadwinner respondents who report no family assets.

Similarly, Bloemen and Stancanelli (2005) estimated the impact of more generous job displacement benefits on food consumption growth (from prior to layoff to 3 months after) in the United Kingdom. Severance pay ('end-of-job payment') had a positive and significant effect on consumption growth as well as debt reduction following job loss. The UI replacement rate was not significant if entered without interactions, but was significant if interacted with the importance of the respondent's income to the household. "… for a household where the head's earnings are the only source of income, a drop in the replacement rate of 10% leads to a 2% fall in food expenditure" (Bloemen and Stancanelli, 2005: p. 443).

Table 3 Consumption losses among involuntarily displaced workers

Study	*Country/data*	*Sample restrictions*	*Consumption losses*	*Remarks*
A. Consumption losses following displacement				
Cochrane (1991)	U.S./PSID	Involuntary job loss	24–27%	
Stephens (2001)	U.S./PSID	Plant closings and permanent layoffs	11.0% (6+ years) 9.8% (all years)	Earnings decline 21.9% (6+ years)
Stephens (2004)	U.S./PSID and HRS	Older workers (age 50 to early 60s) Business closed/moved or laid off	15.0% (PSID) 17.7% (HRS)	Within 1 year of displacement
Browning and Crossley (2008)	Canada/COEP	Plant closure and mass layoff Tenure greater than 10 years Age greater than 40 years	6.4% 10.4% 9.3%	Canadian Out-of-Employment Panel (COEP) total expenditures
Bloemen and Stancanelli (2005)	U.K./LSUS	Unemployed for at least 3 months	17% (simple average)	Living Standards during Unemployment Survey
B. Responsiveness of consumption to job displacement insurance				
Browning and Crossley (2001)	Canada/COEP	Permanent layoff At least 6 months unemployment	0.05 Consumption/UI RR elasticity 0.17 Consumption/UI RR elasticity if no assets and respondent sole breadwinner	Canadian Out-of-Employment Panel (COEP) total expenditure
Bloemen and Stancanelli (2005)	U.K./LSUS	Unemployed for at least 3 months	UI RR effect insignificant except 0.2 Consumption/UI RR elasticity if zero assets, no severance and sole breadwinner	Severance pay has significant, positive impact on consumption
C. Responsiveness of consumption to permanent/transitory earnings shocks				
Blundell et al. (2008)	U.S./PSID and CEX	Distinguish transitory and permanent shocks	0.64 Elasticity of consumption change to permanent income change 0.05 Elasticity of consumption change to transitory income change	Heterogeneity important

CEX, Consumer Expenditure Survey; HRS, Health and Retirement Survey; PSID, Panel Study of Income Dynamics; RR, replacement rate; UI, unemployment insurance.

Blundell et al. (2008) extended this literature (PSID) in a general way, noting that:

> We find some partial insurance of permanent shocks, especially for the college educated and those near retirement. We find full insurance of transitory shocks except among poor households.
> Blundell et al., 2008, p. 1887

These results are consistent with the belief that the temporarily unemployed workers and short-tenured displaced workers find ways to cushion the effects of earnings shocks on household consumption, but that the long-term displaced do not, with the (partial) exception of the college educated and those near retirement.

Apparently, the mixture of private and public severance pay and UI offered in the countries studied does not guarantee consumption stability in the face of job loss among long-tenured workers. Severance pay and, perhaps, unemployment benefit levels do appear to contribute to consumption smoothing. It is, of course, simple to design a system that would insure uninterrupted consumption following job displacement – offer unemployment benefits of unlimited duration equal to the original wage – because the worker would have no incentive to accept a lower offer. Such a plan, however, would insure that the long-tenured displaced workers do not return to work, except in robust labor markets. The policy challenge is to design systems that will better insure the long-tenured displaced workers without wasting their productive capacities. In the remainder of this article, alternative job displacement insurance systems are considered within a standard demand and supply framework.

The Insurance Market

Insurance Demand

The capitalized value of expected job displacement losses of long-tenured workers will vary with discount rates and potential years of remaining work life, but is large for all but those close to retirement. The literature focuses on employer and government efforts to provide consumption smoothing devices, but individual efforts are nontrivial. At the elementary level, multiearner households pool resources, though the pools are generally quite small. Households also adjust labor market behaviors, with other family members entering the workforce to offset the earnings losses of those displaced.

For frequent, small-loss events – temporary layoffs and displacement of short-tenured workers – savings and credit instruments may be quite satisfactory. Saving instruments are abundant in industrialized economies, but third-party borrowing opportunities are naturally limited by the likelihood that the loan will be paid back. (See Gruber (2001) for a description of financial assets upon entering unemployment and Sullivan (2008) for a discussion of access to unsecured credit (credit cards) among the unemployed.) As instruments provided by employers, unions, and especially government have become dominant, studies of these informal approaches have evolved into the question: Do public efforts crowd out informal efforts or do they contribute on net to worker financial security (Cullen and Gruber, 2000; Engen and Gruber, 2001)? Apparently, crowd-out effects are substantial.

Because layoff in the first instance is an employment event, it is natural to imagine the issue within an employment contracting framework. (Reviews of the employment contracting literature include Parsons (1986), Malcomson (1999), and Salanié (2005).) In a simple single-period model, the worker and the employing firm negotiate a contract that specifies (1) the conditions under which the worker will be retained in the firm with corresponding wages and (2) the separation benefits to be paid if the worker is laid off (Parsons, 2014b). Unemployment is an important aspect of this model, and worker utility is correspondingly multidimensional (consumption and leisure). The worker is assumed to be risk averse and the firm to be risk neutral. (In simple cases, two-dimensional (consumption, leisure) 'risk averse' can be defined by an indirect utility function that is concave in income (Stiglitz, 1969), in this case full income – nonearned income plus earnings if the worker devotes all available hours to work.)

A key issue is the severity of the demand shock that will induce the firm to lay off workers. Layoff behavior, or conversely job retention, has been much studied, in part because of the link with firing cost concerns (see Section Insurance Design below). Azariadis (1975), in his seminal work on employment contracting, derived the conditions under which the firm will lay off workers in an economy in which (1) there is no possibility of reemployment and (2) job displacement insurance is not available. His model highlights the insurance value of labor hoarding: workers will negotiate full-employment contracts over a larger domain of shocks.

If demand contractions are sufficiently large, however, layoffs will occur and the displaced worker will find himself or herself unemployed or reemployed elsewhere, often at a lower wage. A complete separation package will then be a combination of (1) wage insurance and (2) UI.

The first-best magnitude of each of these is dependent on the structure of the state utility functions, sometimes labeled von Neumann–Morgenstern utility functions. Insurance redistributes consumption across states, but the utility value of consumption is in general not independent of the amount of leisure available to the worker, and the displaced worker by definition faces 'excess' leisure in the unemployed state. Many design studies use a special case for this utility function, additively separable concave functions of consumption and of leisure. (Early examples include Azariadis (1975), Shavell and Weiss (1979), and Hopenhayn and Nicolini (1997).) This model has the convenient property that, if insurance can be costlessly provided, *consumption will be equal across states in the ideal contract*. If layoffs are justified, the ideal consumption plan can be implemented by

1. *wage insurance benefits* equal to the difference between the earnings of retained workers and reemployed workers, and
2. *UI benefits* equal to reemployment earnings.

This special utility structure insures that search moral hazard problems will arise – consumption is equal across states of nature, while leisure is greater in the unemployed state. (Perhaps to emphasize nontraditional concerns, Blanchard and Tirole (2008) employ a utility model with a constant cash

equivalent value of leisure that induces neither search moral hazard nor firing cost problems (see Section Insurance Design below).)

Insurance Supply

The usual third-party suppliers of insurance products do not exist for job displacement insurance. Instead, three types of insurers are prominent: labor unions, employers, and the government. European trade unions were early pioneers in the provision of UI, but were never able to maintain reserves sufficient to finance benefits when times were hard. (Willoughby (1897) provides an interesting contemporaneous account of these efforts.) These failed efforts induced government intervention, the Ghent system, in which governments essentially financed union benefit programs. (See ILO (1955) for a broader historical review of early public UI programs.) In the US, unions have negotiated guaranteed employment contracts as well as severance pay and supplements to government-supplied UI benefits (supplemental unemployment benefits or SUB plans) (Pita, 1996). That said, today employers and governments are the main suppliers of job separation insurance.

The efficient provision of full job displacement insurance requires information on a variety of processes:

1. Was the worker involuntarily separated and therefore eligible for benefits?
2. Is the worker, while on benefits, actively seeking the next job and willing to accept reasonable job offers he or she uncovers?
3. Has the worker become reemployed, so that benefits can stop?
4. Is the drop in earnings following reemployment the consequence of a decline in wage rate rather than reduced work hours?

The first question is most easily answered by the employer, though the employer's response may be distorted by self-interest, depending on the financing system. For example, if benefits are limited to involuntary separations and partly or wholly paid by the employer, the employer has an incentive to categorize a separation as voluntary. If the layoffs are large scale, involuntary separations are hard to disguise, but that is not the case in small-numbers situations. Indeed, in the U.S. UI system, employers bear a substantial share of the cost of benefits paid out to their own laid-off workers (experience rating), and significant resources are required to adjudicate disputes over the nature of the separation. Conversely, if benefits are wholly paid by the government, the employer may be tempted to report any separation as involuntary, treating generously its own past workers at the expense of other taxpayers, typically firms.

UI requires substantial information following separation. The second and third questions seriously strain employer capabilities, and perhaps even those of governments. Even the conceptual simple task of determining whether the displaced worker has taken another job faces practical difficulties. In more developed economies, for example, undetectable jobs arise in the shadow economy of cash transactions. In less-developed economies, tracking workers across jobs of any sort may be difficult. (For recent estimates of the pervasiveness of the shadow economy, see Buehn and Schneider (2012).) Governments may be efficient at monitoring employment if the shadow economy is small and UI program coverage is broad. In that case, the worker's reemployment would be entered into the system at the time of the next hire, assuming of course unique individual identifiers.

Problem (2) is not easily monitored by any agent and has been the focus of much program design effort. In the simplest case, unemployment involves a release from work, and actual loss UI benefits must be limited in order to induce appropriate search and job acceptance behavior, with the reduced UI benefits partly and imperfectly offset by scheduled benefits (severance pay) (Baily, 1977; Rogerson and Schindler, 2002; Parsons, 2014b).

The provision of wage insurance pivots critically around the last question (4), the answer to which is typically unavailable to the displacing firm and often to the government. (Full reemployment wage insurance would require pooling of the earnings of the winners and the losers, but this has not been seriously proposed. Most policy designers propose a negative option payment – for those who make losses, some fraction of the losses will be paid through premiums from all (Baily et al., 1993). For additional discussions, see Parsons (2000), Kling (2006), and LaLonde (2007).) The U.S. UI system, for example, relies largely on earnings records for eligibility and benefit calculations, and not on work hours. But wage insurance is really wage rate insurance and assumes a return to full-time work. Otherwise it becomes a variant of UI with similar problems. The separation of total earnings into hours and wage rates is not a serious problem in large enterprises, which must themselves accurately track worker activities, but can be more difficult to verify in smaller enterprises. In this environment, wage insurance benefits are likely to be 'scheduled,' that is based on expectation of loss, rather than actual loss.

In broad outline, then, information problems are likely to shift actual loss unemployment provision to the government, and transform the insurance package from UI and wage insurance to (incomplete) UI and severance pay. Severance pay functions as scheduled (partial) UI and scheduled wage insurance.

Insurance Market Problems

Job Search and Offer Acceptance Incentives

The concern that generous UI benefits might discourage return to work has almost certainly limited unemployment benefits in countries that offer unemployment benefits. As a consequence, a great deal of thought has gone into the consideration of alternative mechanisms for inducing appropriate job search and offer acceptance by the unemployed. Two approaches have received attention – sanctions and active labor market policies. Sanctions typically involve monetary penalties, often in the form of reduced benefits, while active labor market policies involve time penalties.

Sanctions

An obvious approach is to impose penalties or sanctions on those who do not behave appropriately. Sanctions can be in the form of fines or, more commonly, reductions in future benefits. (Grubb (2000) provides a review of UI sanctions in OECD countries.) Denying or delaying benefits to workers who quit or are fired from their last jobs before entering unemployment is one such sanction. The withholding of benefits if workers do not undertake, or at least report, reasonable job search effort is another. The penalty may be the same for workers who quit their jobs and those sanctioned for lack of search effort (Grubb, 2000).

The U.S. UI system has search requirements, which vary by state, with the loss of future benefits as the sanction. A plan might require the unemployed recipient to make three employer search contacts in 1 week. Such requirements are not realistically enforceable in the US – it is apparently not possible to confirm or deny a large portion of claimed employer contacts (St. Louis et al., 1986). At a deeper level, it is a rare job that does not require some evidence of enthusiasm for the job by the applicant, but this is something easily withheld and impossible to monitor. Somewhat oddly, demonstration projects in the U.S. suggest that dropping the requirements *entirely* leads to large increases in unemployment duration, but requiring more than one search has no incremental impact on duration (Meyer, 1995).

Abbring et al. (2005) find, for the Netherlands, that the imposition of a sanction does significantly hasten the return to work, and moreover does so even after the current penalty has been lifted. They interpret this result to suggest that sanctioned workers perceive themselves as under extra scrutiny. One might imagine that well-publicized sanctions may have similar threat effects on others.

Active Labor Market Policies

A historically important technique for smoothing earnings shocks in limited-information situations is public works, with the government providing employment to workers in the absence of private demand. Public works, used on a large scale in the US and elsewhere during the Great Depression and often by colonial powers in times of crop failure, remain a potential tool in less-developed countries (Ravallion, 1991). Even if the work yields little product, it assures the provider that the beneficiary is willing to work and is not employed elsewhere. (Pissarides (2010) specifies conditions under which a private employer might undertake the equivalent of a public works project.)

The same approach has been extended to UI beneficiaries under the label 'active labor market policies,' although the work activity might instead involve mandatory training or search activities (see Kreiner and Tranaes (2005) for a discussion and analysis). Search moral hazard arises because workers value leisure as well as consumption, and unemployment by definition includes excess leisure. If the government wants to direct income to the unemployed without discouraging work effort, it can do so by imposing a countervailing work (activity) requirement on the beneficiary. Such requirements are labeled 'ordeals' by Nichols and Zeckhauser (1982).

As Besley and Coate (1992) nicely illustrate, ordeals work best, and perhaps only, if the insurer cares solely about income and consumption and not about worker utility, which would include leisure. For that reason, sanctions and ordeals appear in government-mandated programs, not voluntary contracts in which utility is paramount. Modern applications of this public works approach often soften the edges of the policy by labeling the work activity 'job training,' although the evidence on positive earnings effects of government job training programs is decidedly mixed. The signature of an ordeal is that the activity be mandatory, not voluntary, although gradations exist here. One might conjecture that the more resources the government devotes to the activity, whether job training or counseling, the more effective the program and the less onerous the ordeal.

There is perhaps a natural limit to the ordeal of sanctions and active labor-market policies. Imposing penalties on those one is trying to assist may be preferred to across-the-board benefit limitations, but is otherwise unappealing. In the best of circumstances, the threat of benefit sanctions or mandatory work requirements would induce ideal behavior without the threat ever being acted upon. (See, for example, Black et al. (2003). Such good fortune is perhaps rare.)

Firing Cost Issues

The importance of severance pay in the job displacement package is perhaps reflected in the pervasiveness of severance pay mandates and the voluntary provision of severance where it is not mandated. Economists, however, have regularly expressed concerns about mandated severance pay. (See, for example, Emerson (1988) and Lazear (1990) and the reviews in Heckman and Pagés (2004), Holzmann et al. (2012), and Parsons (2012a).) If employers must self-finance job displacement insurance, they might be tempted to retain workers in low-demand states who would, on efficiency grounds, be released to secure more productive matches elsewhere. Labor hoarding may be excessive.

Firing costs are often associated exclusively with severance pay, but this is a historical accident. In a model in which employers supply all separation benefits and cannot reinsure those benefits in third-party markets, firing costs would be the sum of severance pay and expected unemployment benefits. The concern about severance pay distortions arose with the practice, common in much of Europe, of mandating that firms must provide severance pay, leaving firms to fully fund the mandate. The European unemployment system, in contrast, has no user cost element; firms can lay off workers without any concern that higher benefit payouts to their workers will lead to higher taxes or surcharges. In that situation, firing costs are limited to severance pay.

In the US, severance pay is voluntary and is fully financed by the employer, so the same firing cost concerns arise. UI benefits are fully funded by taxes on payrolls, but the tax rate varies with the UI benefits distributed to the firm's laid-off workers ('experience rating') and will therefore enter firing cost calculations. Although severance pay is less generous in the US than in Europe, the experience rating of unemployment benefits raises the possibility that firing cost distortions may be higher in the US.

As it happens, severance pay alone appears to have only modest effects on labor hoarding, although it is important to recognize that large benefit mandates are found only in

countries in which labor laws are poorly enforced (Parsons, 2012a). Neither do firms engage in active avoidance of severance mandates, a possibility proposed by Lazear (1990). Apparently, they do not. That said, firing cost distortions may be a problem in substantially more generous benefit systems, an important caveat if one believes current levels are inadequate.

Insurance Design

A multiperiod framework permits more complex insurance schemes as well as introducing savings and borrowing strategies. Embedding the insurance contract in a multiperiod context introduces direct effects on severance pay schedules and, more subtly, on UI schedules. We consider insurance schemes in this section and saving and borrowing plans in the next.

Service-Conditioned Severance Benefits

The fact that reemployment wage losses increase systematically with job tenure (**Figure 2**) has the unsurprising consequence that severance benefits are almost always increasing in 'service' with the employer, essentially tenure. In voluntary plans in the US, a benefit rule of 1 or 2 weeks of pay per year of service is common (Parsons, 2005). The same basic weeks-pay-per-year-of-service algorithm, though with greater benefit levels, is common in mandated severance worldwide. See the scatter diagram of mandated benefits at 20 years relative to 5 years (**Figure 3**) for the sample of mandated plans in medium and large countries (1 million or more inhabitants, Holzmann et al., 2012: Annex B). The typical mandate is, however, well in excess of 1 week per year of service. Of the 118 countries with severance mandates and valid nonzero benefit information at 20 years of service, 90 (76%) mandate more than 20-weeks pay (Holzmann et al., 2012: Annex B). The median mandated benefit at 20 years of service in this sample of countries is 33.5-weeks pay.

UI Benefits over the Duration of Unemployment

Of (much) greater design subtlety, multiperiod models introduce interesting new UI benefit strategies. In a multiperiod setting, the benefit algorithm must specify a level of benefits for each week of unemployment. In practice, most government benefit schemes are quite simple. The U.S. benefit schedule has two steps, with zero benefits in the second step. The behavior of unemployed workers at or near the point at which benefits are 'exhausted' has been the focus of considerable empirical study. (Boone and van Ours (2012) provide a summary of this literature as well as their own contribution. See Mortensen (1977) and Meyer (1990) for theoretical and empirical analyses, respectively, of finite duration benefit schemes.) In a number of European countries, benefits are reduced more gently through a transition to social assistance, often means-tested welfare programs (Atkinson and Micklewright, 1991). (In the Holzmann et al. (2012) data, 16 of the 149 medium and large countries had both UI and unemployment assistance (author's calculations from Annex B). Another six had only unemployment assistance.)

Economists have devoted a great deal of attention to the ideal benefit payout stream as a function of unemployment

Figure 3 Mandated severance pay benefits (weeks pay) at 5 years and 20 years of service, 124 countries. Holzmann, Robert, Pouget, Yann, Weber, Michael, Vodopivec, Milan, 2012. Severance pay programs around the world: history, rationale, status, and reforms. In: Holzmann, Robert, Vodopivec, Milan (Eds.), Reforming Severance Pay: An International Perspective. World Bank, Washington, DC, pp. 17–120, Annex B.

spell duration. (Paradigm theoretical studies of optimal UI include Azariadis (1975), Baily (1977), Mortensen (1977), Shavell and Weiss (1979), and Hopenhayn and Nicolini (1997). Holmlund (1998), Karni (1999), and Fredriksson and Holmlund (2006) provide excellent reviews.) A key early finding was that UI benefits should optimally decline with the duration of unemployment (Shavell and Weiss, 1979). The intuition is straightforward. By throwing benefits forward in time in the unemployment spell, workers have less incentive to delay return to work despite currently generous benefits. Reduced future benefits are a threat that may not be realized. Early theoretical contributions, including Shavell and Weiss, assumed away the possibility that the worker could transfer resources across time except through the program under study. The need to repress the possibility of private saving is obvious. The worker, post-separation, has no desire to be squeezed in this way and would likely save early UI benefits in order to supplement low benefits in later periods. (Pavoni (2007) expresses concern that declining benefit schemes in the saving-constrained case might lead to unacceptably low levels of benefits for longer unemployment spells. This problem is less serious if the worker is permitted to save.) This no-saving assumption becomes formally awkward in a job displacement setting in which severance pay is almost certainly part of the optimal vector of benefits. (The fixed-sum benefits may be paid out as a lump-sum or as periodic payments, but without reference to unemployment status.)

Hopenhayn and Nicolini (1997) analyzed an environment in the spirit of Shavell and Weiss, with no private saving or borrowing, but introduced the possibility that the insurer, presumably the government, can pay out additional benefits early and finance the expense by taxing future worker earnings. The optimal benefit scheme will still involve declining benefits, but, at least in the example developed, at a rate much lower than in the Shavell and Weiss model. The penalty for engaging in longer unemployment spells is spread over both lower expected future unemployment benefits and lower future after-tax earnings. This model also unravels if the worker can privately reallocate resources across periods, and perhaps has assets to start – as the worker would, for example, with severance payments.

In what may now be considered an early attempt to apply behavioral economics, great effort has also gone into assessing empirically a quite different, discrete payment plan – reemployment bonuses – which offers a lump-sum reward if a worker takes another job in a specified time interval. An eye-catching bonus to successful early job finders may accelerate job search and acceptance sufficiently that the bonuses pay for themselves. One early demonstration project to test this conjecture, Illinois, raised hope that the approach might be of practical value (Woodbury and Spiegelman, 1987), and led to an ambitious series of demonstration projects that generated much valuable insight into the behavior of the unemployed. (Meyer (1995) provides a thorough review of the demonstration projects and their outcomes.) Alas, the demonstrations provided no support for the validity of the core proposition. Lump-sum bonuses for early job acceptance do not usually pay for themselves.

Saving and Borrowing Strategies

Mandated saving and borrowing options have received considerable attention as *alternative* mechanisms for helping unemployed workers smooth consumption in response to earnings shocks (Feldstein and Altman, 2007; Stiglitz and Yun, 2005). The theoretical advantages of unemployment savings accounts and severance savings accounts are that they should induce neither (1) search moral hazard nor (2) firing cost concerns. The reason of course is that the worker already owns the payout, which means the worker cannot capture additional benefit payouts by (inefficiently) remaining unemployed, and the employer cannot avoid benefit payouts by (inefficiently) retaining the worker on the payroll (Parsons, 2012b).

Savings accounts may be an excellent substitute for earnings insurance *for temporary layoffs* in which the worker returns to the contract firm, presumably at the original wage. UI benefits paid to workers on temporary layoffs amount to externally financed vacation pay for a firm's employees, and are likely to be heavily used (Feldstein, 1976). The puzzle that remains is why workers and governments are so reluctant to embrace the savings approach – even for temporary layoffs. Savings are, however, a relatively poor tool for smoothing consumption among long-tenured, displaced workers. That said, if otherwise uninsured, even large shocks are eased by access to savings and credit markets.

As noted in the last section, the worker's ability to save privately fundamentally changes what the government can accomplish. Penalizing extended unemployment through declining consumption, as in Shavell and Weiss (1979) and Hopenhayn and Nicolini (1997), may not be feasible. If the government administrator can observe assets, the declining unemployment benefit plan can be salvaged if the government is willing to tax away positive assets as they accumulate (insuring that none will have any), though that seems unlikely as a public policy.

Insurance plans and saving and borrowing plans are not mutually exclusive, and can be offered jointly. Worker access to savings instruments changes the profile of optimal UI benefits. In a model with no moral hazard issues, Shavell and Weiss (1979) demonstrated that positive UI benefits should be offered only after assets are depleted, and then at a fixed benefit level. (Unless assets are sufficiently small that they can effectively be ignored.) First exhausting assets and then accessing insurance makes sense in this model because the worker has no alternative uses for the savings (no retirement or bequest, no risk of future layoffs or wage rate declines). Shavell and Weiss (1979) did not analyze the (search-effort) information-constrained case, but provide a two-period model that demonstrates that optimal benefits could either increase or decrease with longer unemployment spells, depending on circumstance such as initial wealth position. Lentz and Tranaes (2005) developed a model of job search and asset choice with fixed unemployment benefits of unlimited duration that generates the plausible prediction that savings will be used to support consumption during an unemployment spell, with search effort increasing as savings dwindle. It is plausible that workers would demand increasing UI benefits across unemployment spells in this situation, and more generally negotiate

benefit plans that are conditioned on asset levels (Rendahl, 2012).

If the displaced worker is able to 'hide' assets, the nature of the optimal benefit stream is apparently highly model-specific. Kocherlakota (2004: p. 541) reported being able to "provide a complete characterization of the optimal contract" if search effort is linear in the probability of securing a job offer (and auxiliary assumptions to deal with the linearity problem are met). "The agent's consumption is constant while he is unemployed, and jumps to a higher constant and history-independent level of consumption when he finds a job." Shimer and Werning (2008)constructed a model with a simple search algorithm and a constant absolute risk aversion utility function, which has the convenient property that the solution, in this case of constant benefits throughout the unemployment spell, does not depend on worker wealth – which makes moot the question of whether assets are observed or hidden. Mitchell and Zhang (2010), in a model in many ways similar to Shimer and Werning (2008), concluded that the optimal time profile of benefits should be increasing over the unemployment spell. As a practical matter, approximately 50% of workers surveyed in the Displaced Workers Survey exhaust their unemployment benefits (GAO, 2012), so the exact shape of the benefit algorithm across unemployment spells may not be as important for permanent layoffs as it could be for temporary layoffs. UI is a fixed sum for UI exhaustees – that is to say, severance pay.

Aging and the Long-Tenured Displaced Worker

Long-tenured displaced workers are, by the very nature of the event, older, and issues of aging and of the job displacement of long-tenured workers overlap. At the simplest level, there is the concern that older workers may be disadvantaged in the labor market. The measured impact of job displacement on older workers who return to work is large and justifies concerns about the welfare of these individuals (Couch, 1998), although perhaps no more than younger workers. Chan and Stevens (1999, 2001) analyzed the consequence of job loss on older workers (HRS). Among workers in their 50s or beyond, reemployment wage losses of displacement workers were on the order of 24% (relative to the not displaced) with a mean duration of unemployment of 12 months (Chan and Stevens, 1999: pp. 212–213).

Measurement of job displacement effects is difficult because a greater fraction of older workers than others never return to work. That may be because jobs are scarce or because older workers have access to a variety of alternative support systems, including disability insurance and private and public retirement plans, which ease withdrawal from the labor force. Borrowing against pensions and other postwork income streams can also smooth consumption during unemployment periods if feasible (Stiglitz and Yun, 2005). Hairault et al. (2012) argue this freedom is critical if the worker is close to retirement.

Recognizing this demographic reality, firms often offer early retirement buyouts, under the belief, apparently true, that workers relatively close to retirement are willing to separate voluntarily with modest inducements (the shadow value of returning to work is low). Public systems also treat older workers more generously, reflecting both (1) concern for older individuals and (2) the possibility that encouraging older workers to leave the labor force will open up jobs for the young (the fixed jobs hypothesis). Early retirement programs, expanded unemployment duration eligibility, reduced active search requirements – all contribute to earlier withdrawal from the workforce (OECD, 2006).

Older displaced workers do apparently respond robustly to these program incentives and in the expected direction. As Tatsiramos (2010: p. 157) summarizes his cross-country findings:

> … in countries with relatively more generous unemployment insurance provisions for the older unemployed, which offer a pathway to early retirement, older displaced workers exhibit lower re-employment and higher retirement rates compared to the non-displaced.

The welfare implications of these incentives and responses are less obvious, and may depend on the macroeconomic model felt to be relevant in the economy.

Job Satisfaction

Howard M Weiss and Kelsey L Merlo, Georgia Institute of Technology, Atlanta, GA, USA

Abstract

Research on job satisfaction, or the positive or negative evaluation one makes about one's job, began in the early 1930s and has been a productive area of research for decades. In this article, the concept is defined, the history of the research on job satisfaction is described, and major theoretical positions and empirical findings are presented.

Definition

Among the various concepts that can describe how people think about and relate to their work, psychologists have found it useful to include an overall evaluative judgment about one's job. This evaluation is labeled job satisfaction and, thus, job satisfaction can be defined as *a positive or negative evaluation one makes about one's job or job situation.* Conceived this way, job satisfaction is an attitude. Therefore thinking about the measurement of satisfaction or developing theories of its causes and consequences are best approached by recognizing that the concept of job satisfaction falls under the broad umbrella of general attitude theory. This has not always been understood and as a consequence, unnecessary confusion about the nature of satisfaction and its relation to related but different concepts like affect has existed. However, more conceptual clarity has developed in the last 20 years, and the definition of satisfaction an attitude or an evaluative judgment has been broadly accepted.

Traditionally, psychologists have made a distinction between *overall satisfaction*, satisfaction with one's job as a whole, and *facet satisfactions*, expressed satisfactions with the aspects of one's job (e.g., pay, supervision, the work one does, etc.). These differences simply relate to the differences in the object of evaluation. In the past, the language surrounding these concepts has created confusion by implying some part–whole relationship among the various attitudes, as if the overall attitude was composed of the facet attitudes. Although beliefs and attitudes about various work features may influence overall evaluations about jobs, they are only one such influence. Attitudes are always evaluations of something, be they concrete objects like coworkers or abstract concepts like jobs or career opportunities, and any element of work experience that is at all discriminable can be an object of evaluation. Understood this way, when psychologists focus on the evaluation of the totality of a job, they are referring to overall job satisfaction. When they focus on the evaluation of a specific aspect of job experience, they are referring to some facet satisfaction.

Psychologists have also developed a number of other related concepts to describe the aspects of work experience, such concepts are commitment, engagement, work subjective well-being, and so on. In some cases, the differences from satisfaction are subtle but important. In other cases, the differences are more apparent than real, as evaluation turns out to be the disguised but essential defining feature. Only one distinction is important to raise in this article and that is the difference between affect (moods and emotions) and satisfaction, as satisfaction has sometimes been erroneously defined as an affective or emotional reaction to one's job. Satisfaction, as an attitude, is an evaluative judgment. Moods and emotions are affective states with discernible beginnings and endings and the subjective experience of particular feelings. Such affective experiences can influence attitudes but they are not equivalent to the attitudes.

Measuring Job Satisfaction

As is typical with attitudes generally, job satisfaction is most frequently measured using self-reports in questionnaire format. Satisfaction is assessed both in research and organizational practice contexts (e.g., organization-specific morale surveys, climate surveys, etc.), and while researchers tend to use a few well-developed, widely available measures, organizations tend to use proprietary measures either developed in-house or by consulting firms.

Measures used in the research community tend to be of two types: overall satisfaction measures or facet-based measures. Overall satisfaction measures ask for overall evaluations of one's job directly. That is, they specifically reference the totality of one's job as the object of evaluation. One popular example is the 'faces' scale (Kunin, 1955), which asks respondents to use a series of scaled, smiling faces to indicate their overall evaluation. The faces response format can be used to measure evaluations of particular facets too, but it is frequently used as a measure of overall satisfaction. Another popular measure is the Job in General Scale (Ironson et al., 1989) patterned after the facet-focused Job Descriptive Index (see below).

Facet measures assess evaluations of specific aspects of job experience (e.g., pay, supervision, coworkers, etc.). Generally, overall satisfaction is derived as a sum of the individual facet evaluations. The two most popular facet satisfaction measures are the Minnesota Satisfaction Questionnaire (MSQ; Lofquist and Dawis, 1969), which assesses 20 job satisfaction facets and is available in both long and short forms, and the Job Descriptive Index (Smith et al., 1969), which measures five facets. These measures are convenient because they assess both facet evaluations and overall job evaluations and have long histories of use. However, the assessment of overall satisfaction through facet summation is problematic because it assumes that people's overall satisfaction is derived from some mental calculation involving the facet evaluations. There is good reason to suppose this not to be true. Indeed, the Job in General Scale for measuring overall satisfaction directly was developed as a response to this concern. In addition to these rigorously developed overall and

facet measures, there are a number of single- and multiple-item assessments of facet and overall job satisfaction that have been developed in an ad hoc manner and appear in the literature.

History of Research on Job Satisfaction

Research on job satisfaction began in earnest in the early 1930s and was heavily influenced both by the economic and employment crises of the depression and by the new developments in attitude measurement (e.g., work by Thurstone and Likert, in particular.) The economic situation provided an important reason for studying employee 'morale,' while the advances in attitude scaling provided an approach to the task, even if that approach was not often followed rigorously.

Interestingly, research published in the 1930s showed an interest in more varied aspects of work experience than what is captured by the construct of job satisfaction. For example, Fisher and Hannah examined the relationship between 'emotional maladjustment' and job satisfaction in their clinical studies reported in their book *The Dissatisfied Worker* (1931). Rexford Hersey (1932), using what would today be called mood checklists, studied the daily rhythms of worker affect and related those rhythms to daily changes in productivity, physiological states, and off-work life events. Hoppock (1935), interested in the far-reaching consequences of the depression, focused his attention on the social implications as opposed to the organizational implications of job dissatisfaction.

Later, interest in worker experience narrowed to emphasize evaluative judgments of the aspects of work, i.e., job satisfaction and the causes and consequences of those attitudes. Perhaps the research most influential for the development of the dominant paradigm was conducted by Kornhauser and Sharp (1932). In their research, conducted at Kimberley Clark, Kornhauser and Sharp laid the foundation for what was to come by using questionnaires to ask about facets of job satisfaction and relating those facets to aspects of performance of interest to management. The examination of work attitudes became the primary vehicle for studying work experience, questionnaires became the primary method, facet measurement became the primary content, and organizational effectiveness became the primary reason for the research. By the end of the decade, an eclectic stew of thinking about worker experience had boiled down to a puree composed of worker attitudes or job satisfaction. Satisfaction became the predominant way of capturing worker experiences and the research after that mostly concentrated on the predictors and performance correlates of satisfaction, how best to measure satisfaction, and the development of theories of satisfaction formation.

The 1940s and 1950s saw mostly empirical efforts to catalog the various work environment features and personal characteristics that predict differing levels of work satisfaction. There were also continued empirical efforts to demonstrate the ability of satisfaction to predict job performance in its various forms. Although even Kornhauser and Sharp (1932) in their landmark study reported an inability of satisfaction to predict performance, there existed a generally accepted belief that workers would perform better and be more motivated in their work, if they found satisfaction in their jobs. The reasons for this assumption were based more on intuition than sound conceptual analysis. Then in 1955, Brayfield and Crockett published an influential review of studies correlating satisfaction and performance and found the relationship to be negligible. Subsequent reviews by Vroom (1964) and Iaffaldano and Muchinsky (1985) came to the same conclusion. Although later reviews (for example, Judge et al., 2001) may be more optimistic about the relationship between satisfaction and performance, by the late 1950s it became clear that more theoretical development of the concept was needed, including better understanding of the development of work attitudes and a clearer picture of the many ways in which employees contribute to organizational effectiveness might be predicted by levels of satisfaction.

In this regard, the 1960s might be considered the 'golden age' of satisfaction research as psychologists mostly abandoned the empirical efforts to catalog the correlates of satisfaction and began to develop influential theoretical positions. In 1959, Herzberg, Mausner, and Snyderman introduced the 'two-factor' theory, which dominated research and practice for over a decade. Important theoretical positions were offered by Porter (1961), Adams (1963, 1965), Katzell (1964), and Locke (1969) in a tradition that Lawler (1973) labeled 'discrepancy theories' to illustrate that they all involved workers comparing assessments of working conditions to some personal standard. Vroom (1964) developed a theory of satisfaction out of his broader expectancy theory of motivation. The 1960s also saw the development of the two most important theoretically driven measurement systems, the Job Descriptive Index (Smith et al., 1969) and the MSQ (Lofquist and Dawis, 1969). Important theoretical developments continued in the 1970s, particularly with the introduction of social information processing theory by Salancik and Pfeffer (1977, 1978), which emphasized the importance of the social context of satisfaction judgments, and the job characteristics model of Hackman and Oldham (1975), which emphasized the importance of features of the tasks that people work on.

Finally, after a period of theoretical and empirical quiescence, the 1990s saw psychology's renewed interest in affective states thereby making its way to the study of work experience. In some ways this helped work psychology come full circle to the initial interests of Hersey (1932) or Fisher and Hanna (1931), broadening discussions of work experience beyond the confines of satisfaction. More importantly for satisfaction research, the interest in affect helped bring clarity to the construct of satisfaction, positioning it as an attitude or evaluative judgment, influenced by but not equivalent to affective states. Important overarching discussions of this were presented by Weiss and Cropanzano (1996) with the presentation of Affective Events Theory (AET) and then in more detail by Weiss (2002). Now, as indicated earlier, job satisfaction is one of a number of psychological constructs used to understand the subjective experiences of workers. A thorough history of the research on job satisfaction can be found in Weiss and Brief (2001).

Consequences of Differing Levels of Job Satisfaction

An overriding impetus for the study of job satisfaction has been a belief that it is an important influence on job performance.

Consequently, the nature of that relationship continues to be an important direction for the application of empirical and conceptual efforts. As employees can contribute to organizational effectiveness in many ways, through their task performance, commitment to the organization, reliability of attendance, provision of support and mentoring, and so on, no single statement can be made about satisfaction and performance. Instead, the importance of work attitudes to performance appears to be a function of what aspect of performance one is referring to.

Initial interest focused on what might be called immediate task performance and by 1955 enough empirical studies of that relationship had been done to justify a review by Brayfield and Crockett. Their conclusion was rather surprising for the time. "It appears that there is little evidence in the available literature that employee attitudes of the type usually measured in morale surveys bear any simple – or for that matter, appreciable – relationship to performance on the job." (1955: p. 408). Later Vroom (1964) reviewing essentially the same literature came to the same conclusion as did an early *meta*-analysis by Iaffaldano and Muchinsky (1985). More recently, a *meta*-analysis by Judge et al. (2001) reported a more moderate satisfaction–performance relationship ($r = 0.30$, corrected). They suggest that the difference is due primarily to methodological differences (Judge et al., 2001). A *meta*-analysis by Harter et al. (2002) found a moderate relationship between employee satisfaction and unit-level performance ($r = 0.22$). Regardless, it is important to note that even the most optimistic results find satisfaction explaining less than 10% of the variance in task performance. Further, most of the data points in these *meta*-analyses are from correlational studies, leaving causal direction ambiguous. Finally, Bowling (2007) suggests that the satisfaction–performance relationship is largely spurious. He found that the relationship between satisfaction and performance dropped to 0.09 after controlling for domain-specific personality traits (i.e., organization-based self-esteem), suggesting that satisfaction may not be causally related to performance. Overall, and contrary to intuition, these results suggest modest to negligible relationships between job satisfaction and task performance.

Employee contributions to organizational effectiveness go beyond the contributions made by immediate task performance and therefore research has also looked at the ability of satisfaction to predict other criteria like job withdrawal (turnover, absenteeism, etc.) and extra-role behaviors (organizational citizenship behavior (OCB) and counterproductive work behavior (CWB)). *Meta*-analyses of studies examining satisfaction–turnover relationships generally produce findings similar to those for task performance, moderate but not substantial. For example, Carsten and Spector (1987) found that turnover was related to satisfaction ($r = -0.26$, corrected) and Tett and Meyer (1993) found that turnover intentions and withdrawal intentions were highly correlated with job satisfaction ($r = -0.58$, corrected), but observed turnover less so ($r = -0.24$). A number of other *meta*-analytic studies found relationships of a similar magnitude (Cotton and Tuttle, 1986; Fried et al., 2008; Griffeth et al., 2000; Hom et al., 1992; Podsakoff et al., 2009). Overall, satisfaction is most strongly related to turnover intention, not actual turnover. The attenuated relationship between intentions and behavior may be due to a myriad of other factors that are outside of the individual's control (i.e., ability to get another job).

Similar to the satisfaction–turnover relationship, satisfaction has been weakly related to absence duration ($r = 0.09$) and absence frequency ($r = -0.18$; Scott and Taylor, 1985). The restricted relationship between absenteeism and satisfaction may be due to the employee's ability to express such behaviors (i.e., strict absence policies).

In the 1980s, interest shifted to behaviors that were outside of the formal job requirements, such as OCB (see Bateman and Organ, 1983; Smith et al., 1983). OCBs, broadly defined as organizationally useful behaviors that are not formally prescribed by formal job requirements, appear to be moderately correlated with satisfaction ($r > 0.16$; Dalal, 2005; LePine et al., 2002; Organ and Ryan, 1995). CWBs, or behaviors intended to harm coworkers or the organization as a whole, can be considered the opposite of OCBs. Mount et al. (2006) found significant path coefficients between satisfaction and organizational CWBs ($r = 0.41$) and interpersonal CWBs ($r = 0.40$), and Dalal (2005) found a moderate relationship between satisfaction and overall CWBs ($r = -0.37$, corrected). In comparison to in-role behaviors, more substantive effect sizes for OCBs and CWBs may be due to the greater level of control that the employees have over these behaviors. OCBs and CWBs are not strongly regulated behaviors, and thus allow employees more latitude in expression.

Harrison et al. (2006) have argued that this behavior-by-behavior approach to satisfaction consequences is inconsistent with basic attitude theory. Working from the compatibility principle of attitude theory, they argue that overall job satisfaction, as a general attitude, should be a better predictor of an aggregated index of employee contributions than of any single behavior. In a very creative *meta*-analysis, where they combine results for both withdrawal and extra-role behaviors, they conclude that the expected relationship of overall satisfaction with an integrated index of contribution approached 0.60. Their work is important because it shows a utility for job satisfaction that has been heretofore hard to find and because it demonstrates the usefulness of incorporating attitude theory into the study of job satisfaction.

Finally, interest in satisfaction is not driven entirely by organizational considerations as there is reason to believe that job dissatisfaction has negative effects on mental health. For example, a *meta*-analysis by Lee and Ashforth (1996) found significant relationship with satisfaction and Maslach's (1982) three dimensions of burnout: emotional exhaustion ($r = -0.31$, corrected), depersonalization ($r = -0.44$, corrected), and personal accomplishment ($r = 0.29$, corrected). Further, a *meta*-analysis by Faragher et al. (2005) found that satisfaction is related to anxiety ($r = 0.42$), depression ($r = 0.42$), and self-esteem ($r = 0.43$), suggesting that satisfaction at work can be meaningfully related to employee's mental health.

Predictors of Job Satisfaction

Organizational research has had a long tradition of examining the predictive correlates of job satisfaction, with interest in predictors across populations and for specific populations (e.g., nurses, firefighters, teachers, etc.). The result is a literature

of thousands of studies demonstrating that this work feature or that personal characteristic correlates with job satisfaction.

Judge and Kammeyer-Mueller (2012) found it useful to organize the most studied work environment predictors of job satisfaction into four broad categories: the nature of the work itself, the support from coworkers, leader quality, and organizational practices. Evidence exists for the importance of experiences in each of these categories.

Of primary importance among work-related factors is the nature of the work itself. Since the introduction of the Job Characteristics Model (Hackman and Oldham, 1976) of satisfaction and motivation, empirical studies consistently show that when people work on jobs, they report as being more complex, requiring more skills, providing more intrinsic feedback, and so on, they also report higher levels of job satisfaction. In addition, interventions that change jobs to enhance these characteristics generally enhance reports of satisfaction as well. Related to the structure of work, but not the specific task per se, is research on role conflict and role ambiguity. Both role conflict, the extent of incompatible job demands, and role ambiguity, uncertainty concerning job responsibilities, are consistently correlated with reports of job dissatisfaction. Importantly, conflict between work and nonwork roles is also a consistent predictor of dissatisfaction. Kossek and Ozeki (1998) found a negative relationship between all types of work–family conflict and satisfaction ($r = -0.31$), suggesting that problematic work and nonwork relationships are detrimental to satisfaction.

Social interactions in the workplace, both with coworkers and with supervisors, are well-known predictors of job satisfaction. Not surprisingly workers report that the degree of support they get from their coworkers is an important influence on the extent to which they like their jobs as is the degree to which their supervisors show concern, consideration, and respect for them (Judge and Kammeyer-Mueller, 2012).

Organizational practices and policies also influence satisfaction. For example, Baltes and colleagues investigated the differential effect of nontraditional work schedules on satisfaction (Baltes et al., 1999). Flextime schedules allow individuals to decide when to arrive and leave from work. Compressed workweeks condense the workweek to less than 5 days by increasing the number of hours per day. A compressed schedule was more strongly related to satisfaction ($r = 0.28$) than a flextime schedule ($r = 0.07$). Much research has shown that being treated in a just and fair manner correlates with reported job satisfaction. Interestingly enough, while most people would think that pay levels are the single most important influence on satisfaction, *meta*-analytic results suggest that pay may only be weakly related to job satisfaction (Judge et al., 2010).

Personal antecedents, such as personality, also predict satisfaction. Bruk-Lee et al. (2009) found that job satisfaction was positively but weakly related to the Big Five personality traits (Goldberg, 1990) of conscientiousness, extraversion, and agreeableness ($r \geq 0.12$), negatively related to neuroticism ($r = -0.25$), and not related to openness to experience. Satisfaction was also related to trait positive affectivity ($r = 0.41$) and negative affectivity ($r = -0.25$) (Bruk-Lee et al., 2009). Another *meta*-analysis (Connolly and Viswesvaran, 2000) found similar relationships between positive and negative affectivity and satisfaction.

The ability to review the thousands of studies on the predictors of job satisfaction is clearly beyond the scope of this article, but there is no compelling necessity to do so. The purely empirical database, the observation that this factor or that variable predicts satisfaction, might have some practical value in a particular context but it provides little organizing explanatory insight into the nature of work attitudes or their consequences. This conclusion has not gone unnoticed by job satisfaction researchers, and as a result a rich history of theoretical activity has developed side by side with the purely empirical database.

Theories of Job Satisfaction

Two general points can be made about the broad array of theoretical positions developed regarding job satisfaction. First, although job satisfaction is an attitude held about one's job (or the aspects of one's job when referring to facet satisfactions), very few of the major theoretical positions are informed by basic attitude theory (but see work by Schleicher et al., 2011; Harrison et al., 2006; as a notable exceptions). Second, most theoretical positions focus on developing a causal structure for satisfaction, instead of trying to place satisfaction within a broad nomological network of causes, consequences, moderators, and so on. Interestingly, all of the theoretical approaches have received some empirical support, partly because they are mostly complementary rather than antagonistic, partly because they each touch on some element of the truth, and partly because they are infrequently stated or tested in ways conducive to disconfirmation.

Theories of job satisfaction can be placed within four broad categories: cognitive judgment theories, social influence theories, dispositional theories, and affect theories. Historically, cognitive judgment theories are the oldest positions and affect theories are found more recently. These theoretical positions are best understood as presenting differences of emphases, not incompatibility. For example, affect theories like AET generally include a role for personality.

Cognitive judgment approaches dominated the theoretical landscape in the 1960s; and although they are more rarely researched today, they still form an implicit framework for many discussions of satisfaction. Locke's (1976) value-based theory is perhaps the most influential, but theories with a similar structure were offered by Porter (1961) and Katzell (1964), among others. Although each of the theories has unique elements, a general framework can be described. In this framework, the work environment is perceptually organized as a set of discrete concrete or abstract features (e.g., coworkers, pay, supervisors, career opportunities, etc.). Workers have a corresponding set of standards that they use to evaluate the features directly or the outcomes derived from the features (i.e., the pay I receive compared to the pay I desire or expect). Finally, perceptions are matched to standards to yield facet satisfactions. Overall satisfaction is derived from the combination of facet satisfactions.

More recently, a variant of the discrepancy approach can be found in fit theories of satisfaction. Fit can be defined as "the compatibility between an individual and a work environment that occurs when their characteristics are well matched"

(Kristof-Brown et al., 2005). In a *meta*-analysis of research on fit, Kristof-Brown et al. (2005) found support for the contention that the degree to which job and organizational demands match personal skills, need, and values predicts job satisfaction. Fit theories have a 'matching' structure similar to those found in cognitive judgment theories, although judgment theories postulate specific cognitive processes while fit generally does not.

Social influence theories, most notably represented by social information processing theory (Salancik and Pfeffer, 1977, 1978), give emphases to the role that the social environment has in influencing judgments about work. That is, they postulate that attitudes of coworkers can influence perceptions and evaluations of particular features of one's job as well as overall evaluations of the job as a whole. In this sense, social influence theories are not alternatives to cognitive judgment theories but rather help understand how the perceptions that are critical to these judgments are influenced by the social environment. Not surprisingly, research has consistently supported these social influences on work perceptions and evaluations.

Dispositional approaches focus on personality characteristics as influences on satisfaction. As described by Weiss and Cropanzano (1996), the basic idea is that "to some degree, a person's job satisfaction reflects his or her general tendency to feel good or bad about all aspects of life and this general tendency is independent of the specific nature of the job" (p. 7). Evidence for the position is found in tendencies for satisfaction to show some stability across time and jobs and for satisfaction to correlate with established personality constructs. The most notable theoretical position in this area is core self-evaluations (CSE) theory (Judge et al., 1997). CSE represent fundamental evaluations of the self and include personality characteristics of self-esteem, self-efficacy, locus of control, and neuroticism. Research supports the relationship between the CSE composite and job satisfaction.

In the 1990s, the popularity of research on job satisfaction gave way to a new interest in affective states like moods and emotions. However, the new-found interest in true affect did not lead to the disappearance of thinking about job satisfaction. Instead, it helped make that thinking more precise. An important theoretical position in this domain is AET (Weiss and Cropanzano, 1996) that attempts to clarify key concepts in satisfaction and affect research. In particular, it explicates differences between satisfaction, as a relatively stable attitudinal evaluation of one's job, and moods and emotions as transient affective experiences (see also Weiss, 2002), and it discusses how discrete affective experiences influence overall judgments like satisfaction. It also draws a distinction between affect-driven behaviors (criteria driven by immediate affective states like moods and emotions) and judgment-driven behaviors (criteria driven by evaluative judgments like satisfaction). Now, these distinctions between affect and attitude are well accepted and their interrelationships represent a productive area of research.

Summary

Jobs satisfaction, the overall evaluative judgment one has about one's job, has a long and rich history in organizational research and practice. In some ways it is seen as the enduring 'person side' of such research, in contrast to performance interest of much organizational research. Even this characteristic is flawed because, historically, much satisfaction research was driven by supposed performance implications. Nevertheless, over the long history of work psychology, satisfaction has generally carried the load for research on work experience. Today work experienced is captured by a plethora of related constructs like emotions, moods, engagement, commitment, and so on. Still, as part of this umbrella of work experience concepts, satisfaction remains an important way to describe worker–employer relationships of interest to researchers and management.

Joint Action

Margaret Gilbert, University of California, Irvine, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

For the purposes of this article, a joint action is the action of two or more people. Thus, two or more people may hold a conversation, go hiking together, and so on. Joint actions are central to everyday life, but it is not easy to say precisely what they amount to. A variety of accounts have been envisaged by theorists. This article reviews some of the best-known accounts, with special reference to their capacity to explain the nature and source of the entitlements and obligations associated with joint actions. Some of these proposals see the core of any joint action as an array of personal intentions in favor of the joint action, where personal intentions are expressible by the individuals they characterize in sentences of the form 'I intend….' Others have argued that something else lies at the core of any joint action. Thus, John Searle contends that each participant must manifest what he refers to as "collective intentionality," which is a matter of an individual 'we'-intending, as opposed to his or her having a personal intention. Margaret Gilbert argues rather that joint actions are grounded in an appropriate "joint commitment" of the parties. An appeal to joint commitment provides an explanation of the entitlements and obligations of joint action. Some, including Michael Bratman, appeal rather to a complex moral principle to provide an explanation of these entitlements and obligations.

Some Initial Considerations on Joint Action

Joint Action Need Be Cooperative Only in a Broad Sense

Joint action is not necessarily a matter of amicable cooperation. We may be quarreling with one another or engaged in a fight. Quarreling and fighting are species of joint action. Though it need not be amicable, there is clearly a broad sense in which joint action is always cooperative or collaborative. I cannot quarrel with you unless you quarrel with me; I cannot fight with you unless you fight with me. If you refuse to take me seriously we cannot quarrel. If you lay down your arms, we are no longer fighting.

Obligations and Entitlements in the Context of Joint Action

Informal observation of the way people behave when doing things together makes it clear that the parties often rebuke one another for not acting accordingly. Such rebukes are commonly understood to be in order. For example, Jill and John are going for a walk, John begins to lag behind, and Jill rebukes John for doing so. John understands that, in the context of their walk, Jill has the standing to rebuke him.

Less punitive responses are also commonplace, and routinely understood to be in order. For example, Jill asks John why he is lagging behind. John may not like being questioned like this, but he does not dispute that Jill is in a position to question him. Or, Jill tells John to hurry up, in order to spur him into appropriate action. John understands that she is in a position to do so. He does not say 'Who are you to tell me what to do?'

Underlying these diverse responses is the understanding that participation in a joint action somehow entitles each of the parties to relevant actions from the other or others. In related terms, each party is obligated to the others to act accordingly. In other terms again, he or she owes them appropriate actions. If one party does not produce the relevant actions, therefore, the others have the standing to question that party, and so on, as they see fit.

A further point is this. Suppose John and Jill have set out together on a 5-mile hike. At some point along the way, John gets tired. He announces to Jill that he is turning back. If he does this, then, failing some special background understandings, something is amiss. It would be different if he asked for Jill's concurrence with his turning back. In general terms, absent special background understandings, no one party to a joint action has the power to determine that the joint action is at an end, or to change its established course. If one party acts as if he or she has that power, something is amiss.

Inferences from Statements about What We Are Doing

From 'We are on a 5-mile hike' and 'In order for us to hike 5 miles, I must hike 5 miles,' it seems that John can infer that he has reason to hike 5 miles. Notably, it is not obvious that there need be any interposition in this reasoning of a premise about John himself. For instance, it is not necessary for John to add that he wants to hike for 5 miles with Jill.

Two Central Questions

A satisfying account of joint action will incorporate an explanation of the observations just given. Two related questions deserve emphasis.

What States of the Participants Are Involved in Joint Action?

When two people are involved in a joint action, what must be true of each of them? Must they, for instance, personally intend to act as is necessary for completion of the joint action? This may seem to be an obvious assumption, and many theorists have assumed something like it. Often they put things initially in terms of an underlying joint intention, then parse this in terms of personal intentions of the parties. As we shall see, serious problems attend this approach.

Of What Kind Are the Obligations and Entitlements Associated with Joint Intention?

The parties to a joint action understand their participation to entitle each of them to actions in conformity with the relevant joint intention. What kind of entitlement is at issue? One might assume that it is moral entitlement founded on moral principle. On the other hand, it may seem that joint action is too basic and primitive a phenomenon to require moral understanding in its participants. It is certainly not obvious that it does require such understanding. Indeed, it seems possible that those with little or no moral perspicacity are both capable of joint action and of understanding that they have the entitlements in question when engaged in such action.

A related point is that those who engage in morally wrongful joint actions with the understanding that their actions are morally wrong may take themselves to have the standings discussed earlier. Thus, one bank robber may rebuke another for holding back at some point, and be understood by his partner to have the standing to do so, though morally speaking his holding back may be the right thing for him to do, as he knows.

Accounts of Joint Action in terms of Meshing Personal Intentions

Michael Bratman sees the core of a joint action as a joint (or, in his terms, 'shared') intention which, he argues, is constituted by personal intentions of a particular kind (Bratman, 1999 contains some central articles). A somewhat simplified version of Bratman's account of joint intention runs as follows. We jointly intend to go for a walk if and only if (a) (i) I intend that we go for a walk, (ii) you intend that we go for a walk; (b) I intend that we go for a walk in accordance with and because of (a) (i) and (ii), and you intend likewise; and (c) (a) and (b) are common knowledge between us.

As to the 'common knowledge' in condition (c), what is intended is, roughly, that (in the example) the fact that conditions (a) and (b) are fulfilled is completely out in the open as far as the two people involved are concerned. (For the first published discussion of 'common knowledge,' see Lewis, 1969.)

There are several problems with an account of joint action in terms of joint intention on Bratman's account. Two will be detailed here. Analogous problems arise for accounts of joint action that are broadly in the spirit of Bratman's proposals.

One problem has to do with the entitlements associated with joint action as such. It does not appear that anyone is entitled to relevant actions from anyone else just by virtue of the satisfaction of the conditions laid down in Bratman's account of joint intention. Thus my intending that we do something, and intending that this occur by virtue of my so intending and you so intending, does not seem to entitle you to any particular action from me, or vice versa. Nor does the fact that my various intentions are common knowledge between us seem sufficient to bring any such entitlement into existence. The fact that you have similar intentions, as is common knowledge between us, does not seem to change things as far as anyone's entitlements go.

If you know that I intend that we go for a walk, and have reason to think that I will not change my mind, then there is a sense in which you are 'entitled to expect' that I am going to make the appropriate contribution to our walking together. But the quoted phrase just means that you have a good basis for predicting that I am going to act thus. It does not mean that you are entitled to my acting thus in such a way that rebuking me, for instance, is in order.

In related discussion, Bratman has invoked a complex moral principle to argue for the presence of the relevant entitlements in many situations in which his conditions on joint intention hold. The principle in question is the 'principle of fidelity' proposed in Scanlon (1990) and elsewhere to explain the obligations of those who make promises. This principle runs as follows (Scanlon, 1990: p. 208): If (a) A voluntarily and intentionally leads B to expect that A will do x (unless B consents to A not doing x); (b) A knows that B wants to be assured of this; (c) A acts with the aim of providing this assurance, and has good reason to believe that he or she has done so; (d) B knows that A has the beliefs and intentions just described; and (e) A intends for B to know this, and knows that B does know it; and B knows that A has this knowledge and intent; then, in the absence of some special justification, A must do x unless B consents to his not doing so.

As Bratman allows, Scanlon's principle of fidelity is not applicable in all situations where there are joint intentions on his account of them. The principle is applicable to the parties, Bratman assumes, if each makes a prior promise to the others; but this is not always the case when there is joint intention and action. Given that joint action by its nature entitles the participants to conforming actions, then appeal to Scanlon's principle will not rescue an account of joint action in terms of joint intention in Bratman's sense.

Another problem with an appeal to Scanlon's principle in this context is that even when it does apply, it is by no means clear that the parties owe one another actions appropriate to the joint action in question, in the sense of 'owe' that is in question here. See Gilbert (2004). This concern also applies to Alonso's appeal to a moral principle of reliance in Alonso (2009).

A further problem with an account of joint action in terms of joint intention in Bratman's sense is that it does not explain the need for the concurrence of all parties in order to terminate the joint action. One with a personal intention is in a position to change it unilaterally. It follows that an individual who is party to a joint intention in Bratman's sense is in a position unilaterally to do away with one of the foundational personal intentions at any time. There is no need for the permission of the other party or parties.

Appeals to a Set of Personal 'We-Intentions'

John Searle has claimed that at the core of joint action lies irreducible states of mind of each participant expressible by utterances of the form 'We intend to do such-and-such' (see, for instance, Searle, 1995; also Sellars, 1963). These 'we-intentions' are irreducible in the sense that they cannot be reduced or broken down into thoughts about what 'I intend' and what 'you intend.' Searle's central concern is to describe the inner or subjective side of joint action with respect to each participant. He does not focus on the question: when is a given 'we-intention' appropriate? What he writes at one point

suggests that, in his view, one person's 'we-intention' is correct as long as the other person or persons in question have corresponding 'we-intentions' of their own. This particular proposal does not seem to be right, if 'We intend to do such-and-such' is understood in accordance with everyday understandings about joint intention.

Suppose that Ben is currently thinking, with respect to himself and Elaine, 'We intend to get married.' Elaine is in a similar position. According to the proposal under discussion, it follows that each one is correct in thinking 'We intend to get married.' Yet according to everyday understandings it would not be plausible to claim that, solely by virtue of the facts described, Ben and Elaine jointly intend to get married. If one learned that they had never discussed the matter, for instance, one would judge that their thoughts were not properly grounded.

In addition to such concerns, it is not clear that those with corresponding we-intentions owe each other corresponding actions. Nor is it clear that the concurrence of all parties is necessary in order to terminate a joint action, on this account.

A Role for Joint Commitment

Joint Commitment

Margaret Gilbert has proposed that the core constituent of a joint action is a pertinent joint commitment (see Gilbert, 2000). The nature of joint commitment as Gilbert understands this will now be explained.

To be committed to do A in the relevant sense is to have sufficient reason to do A. This means that, all else being equal, one will act in error should one not do A. According to Gilbert, if Jane decides to go shopping this afternoon, she is thereby subject to a commitment to go shopping then. She is not subject to such a commitment if she is merely inclined to go shopping or hopes to do so.

Jane's decision creates what Gilbert calls a commitment 'of the will.' It is a 'personal' commitment of the will, the will in question in this case being that of Jane herself. A personal commitment of the will is the creation of the person in question, who is in a position unilaterally to rescind it.

According to Gilbert, there are both personal and joint commitments of the will. A joint commitment of the will is not a conjunction of corresponding personal commitments of each party. Rather, it is a commitment of all the parties by all the parties. A joint commitment requires the participation of each party in its creation in one way or another.

Without prior authorization, no one can unilaterally rescind or dissolve a joint commitment: all must rescind it together. Otherwise it stands as a constraint on the parties. A joint commitment can be violated by one party alone, but this is precisely a matter of violation as opposed to dissolution. Unlike those who rescind or dissolve it, the violator acts against a standing joint commitment.

There are both basic and derived forms of joint commitment. In order to create a joint commitment of the basic type, each party must express to the rest his or her readiness to create with them a particular joint commitment. When this has been done in conditions of common knowledge, the relevant joint commitment is in place. Derived forms of joint commitment will be discussed shortly.

Gilbert has argued that a pertinent joint commitment helps constitute not only joint goals and intentions but also joint or collective beliefs, social rules, and many other central social phenomena (see Gilbert, 1989, 1996, 2000). With respect to the constitution of joint action, she initially invoked a joint goal, and then a joint intention. More recently she has again invoked a joint goal (see Gilbert, 2006: Chapters 6 and 7). The choice in question is not crucial for present purposes. It will be assumed in what follows that a joint intention is at issue.

On Gilbert's account it is necessary and sufficient for two or more people jointly to intend to do such-and-such that they are jointly committed to intend as a body to do such-and-such. Spelling this out: they are jointly committed together to emulate, in relevant ways, one who intends to do such-and-such, by virtue of the actions of each. Actions in this context include utterances. In Gilbert's technical terminology a joint commitment to intend as a body to do such-and-such is necessary and sufficient, by definition, to create a "plural subject" of the intention in question. Thus we intend to do such-and-such, if and only if we constitute a plural subject of intention.

How do people express to one another their readiness to be jointly committed to intend as a body to do something? There are many such ways. Among these are such humdrum verbal exchanges as 'Shall we go for a walk this afternoon?' with a following 'Sure, let's.'

Joint commitments are not necessarily set up through verbal exchanges. Two men who jump into a rowing boat in hot pursuit of a fugitive may signal by their gestures and utterances that, in effect, each is ready to be jointly committed with the other to intend as a body to row to where the fugitive is hiding. As each moves the oars in light of their ensuing commitment, they engage in the joint action of rowing the boat.

In principle, it may take some time for a particular joint commitment to be established. Each party's readiness to be party to the joint commitment may be made clear only gradually and over the course of many interactions with the other people in question.

Derived Joint Commitments

The foregoing examples of the formation of a joint commitment involve joint commitments of the basic type. Here is an example involving a derived joint commitment. Don asks his wife Sally 'Where are we going on vacation this summer?' He presumes that though he is unaware of any vacation plans, there may already be one, and Sally will know what it is. This presumption is based on the existence of a background joint commitment of the basic type. Don and Sally are jointly committed to accept as a body that Sally may make vacation plans for the two of them. With this background commitment in place, Sally is in a position unilaterally to create joint vacation plans for the two of them. Thus, by virtue of the background joint commitment and Sally's unilateral decision, Don and Sally may take on a derived joint commitment such as the joint commitment to intend as a body to go to Spain this summer. Another example: Don has been authorized by a basic joint commitment of the two to decide on the end point of his and Sally's hike. Sally asks him: "Where are we heading?" She asks, in effect, for the content of a derived joint commitment

whose content is so far unknown to her, a joint commitment that may well have been established already.

Large Populations

Members of large populations, such as the many inhabitants of a large island, are unlikely to know one another personally, or even to know of one another as individuals. If there are population-wide joint commitments in such populations, this will be through expressions of readiness to be jointly committed with all others with a certain common feature, such as 'those living on this island.'

By virtue of background joint commitments of the kind discussed in the Section Derived Joint Commitments, the members of a large population can have a particular joint intention in Gilbert's sense, though many of the members do not know of the intention in question. This accords with everyday understandings according to which it may be said that, for instance, a particular country intends a particular action, without it being assumed that everyone in that country knows of the intention, or indeed of the ensuing action.

Those who form intentions for the whole population may be authorized to ensure that these intentions are implemented. Their implementation need not involve all members of the population, in order that the action in question be considered an action of the population as a whole.

Obligations and Entitlements of Joint Commitment

Gilbert has argued at some length that those who are jointly committed in some manner are obligated to one another to act accordingly, and correspondingly entitled to such action from the others (see Gilbert, 2000; also Gilbert, 2006: Chapter 7). A brief argument for her position might note that if one violates a commitment that is joint, it is evident that one is answerable to the other parties to the commitment, who can observe that one has violated 'our' commitment as opposed to a commitment of one's own. They have a clear basis for questioning the violator and for administering rebukes on their own behalf. This implies that the parties to a joint commitment are entitled to conformity from the other parties. These others have corresponding obligations to conform: they are obligated to all parties to the commitment, their obligation being to conform to the commitment.

This and related arguments are arguments from the nature and structure of joint commitment. It may thus be best not to think of the relevant entitlements and obligations as moral entitlements and obligations. All that one needs to understand, in order to understand that they exist, is the nature of a joint commitment. One need not appeal to the value of anything such as, in the case of Scanlon's principle of fidelity, the value of what Scanlon refers to as 'assurance.'

Gilbert's account of joint action offers an explanation of how those who act together have associated entitlements to conformity from one another. These entitlements come from the constitutive joint commitment. There are associated entitlements to ask questions, rebuke one another, and so on, should deviation from the constitutive joint intention be mooted. Gilbert can allow that in some situations where there are joint intentions it is morally permissible not to act in accordance with them. Such situations may include those where one party coerced another into participating in the relevant joint commitment, and those where the joint commitment is to intend something immoral. All things considered, then, it may be morally permissible not to fulfill the relevant obligations of joint commitment. This does not entail that those obligations no longer exist. They exist as long as the sustaining joint commitment exists (see Gilbert, 1996).

Explaining Inferences from 'We Are Doing…'

The plural subject account of joint action provides an explanation of how from 'We are rowing to the other side' and 'My rowing faster will best facilitate our rowing to the other side,' I can infer 'I should row faster' without the interposition of some premise about myself, such as a premise stating that I personally want to row to the other side. My being party to the relevant joint commitment gives me reason to row faster if this will best facilitate our rowing to the other side. I need have no personal desire, inclination, or attitude in favor of our doing this.

Joint Action and Related Phenomena

Gilbert has argued that those who participate in joint actions on her account constitute a social group in a central sense of the term, though the group may be small and transient (Gilbert, 1989). Indeed, she argues, any plural subject in her sense constitutes a social group. List and Pettit (2011) discuss constraints that are necessary, in their view, for a persisting group to constitute a genuine agent.

On Gilbert's joint commitment account of social groups, it can be argued that obligations of a special kind are part and parcel of group membership. This makes it possible to bring Gilbert's plural subject theory of joint action and related phenomena to bear on a classic question of political philosophy, the question of political obligation. Is there an obligation to obey the laws of one's own country in particular, and if so, what is the source of this obligation? Evidently, one possible source is participation in a joint commitment (see Gilbert, 2006).

The topic of joint action is relevant to the topic of collective moral responsibility (see the essays in French and Wettstein, 2006). In this connection Gilbert has argued that, given her joint commitment account, it may sometimes be reasonable to ascribe moral responsibility for a joint act to the group whose act it is. The moral responsibility of particular group members is then a separate matter. This perspective on joint action allows for the intelligibility of a common phenomenon: the experience of pride or guilt over the actions of one's group, as opposed to one's own actions (see Gilbert, 1996).

The Nature and Role of Agreements

Another theorist who has written extensively on joint intention and action is Raimo Tuomela. In Tuomela (1984), he put what he called 'we-intentions' at the center of an account of joint action. Each party to a joint action must have a relevant we-intention. Tuomela's complex definition of a we-intention runs roughly as follows: a member Ai of a collective G

we-intends to do X, where X is some act of G, if and only if (a) Ai intends to do his own part of X, given that every member of G will do his own part of X; (b) Ai believes that every member of G will do his own part of X; and (c) there is a mutual belief in G to the effect that (a) and (b).

Tuomela (1995) introduces the "underlying assumption that we-intentions are formed in a process involving the making of an explicit or implicit agreement (or at least believed agreement)" (p. 127). Assumed agreements determine what joint action is afoot, if any; we-intentions ensue.

Clearly, agreements are a paradigmatic context for the production of joint intentions and actions. However, as the example of the rowers pursuing a fugitive suggests, agreements as these are ordinarily understood and are not essential. If one says that there is an implicit agreement in such cases, the question arises as to what precisely this claim amounts to, since an implicit agreement does not seem to be an agreement proper.

One might do well to start with an account of paradigmatic agreements. There has been less concentrated analytical focus on such agreements than might have been expected, given the undoubted importance of agreements within the scheme of everyday social concepts. A standard claim, perhaps echoing statements in contract law, has been that an agreement is an exchange of promises. Gilbert has argued at length against this view, on one interpretation of it. She has proposed that typical everyday agreements are, in effect, joint decisions, where the core of a joint decision is a joint commitment to endorse as a body the action plan in question (see Gilbert, 1996: Chapter 13; also Gilbert, 2006: Chapter 10).

Suppose that Phyllis and Joe jointly commit to endorse as a body the decision to get married next year. Presumably, it is reasonable then to regard them as jointly committed to intend as a body to get married next year. Given Gilbert's account of agreements and joint intentions, then, agreements give rise to joint intentions, providing a basis for joint action. Agreements are not necessary for joint action, however, insofar as a joint commitment to intend as a body can be brought into being in the absence of a joint commitment to endorse as a body a certain decision. This accords with the way the relationship of agreements to joint actions is commonly understood.

Individualism, Holism, and Joint Action

Annette Baier has objected to the "individualistic bias" she finds in recent work on joint intention and action (see Baier, 1997). She objects in particular to the assumption that multiperson actions are constructed out of single persons, their abilities, and intentions. Baier proposes that doing things with others is more basic than doing things alone. To say this, however, is not yet to explain what doing things with others amounts to.

Clearly, the range of existing accounts of joint intention and action is wide. They include accounts in terms of personal intentions, with appeal to moral principles such as Scanlon's principle of fidelity to account for the associated entitlements and obligations. (Both Bratman and Tuomela appeal to Scanlon's principle.) They also include Gilbert's account, which derives the associated entitlements and obligations from a joint commitment. Gilbert's account goes beyond what she refers to as singularism, insofar as a joint commitment in her sense is not simply a conjunction of personal commitments (see Gilbert, 1989).

Accounts that make personal intentions central accord with the approach to social phenomena of sociologist Max Weber, who put at the center of his fundamental sociological concepts the concept of an action that is oriented to the actions of others (called by Weber (1922) a "social action"). They harmonize well, also, with the classical ways of characterizing social processes in terms of the mathematical theory of games. Gilbert's plural subject account of social phenomena accords rather with the approaches of Emile Durkheim (1982) and Georg Simmel (1971), among sociologists, and of Jean-Jacques Rousseau (1983) and other political philosophers who invoke an actual contract at the base of a human society. (Gilbert (1989), proposes an interpretation of Durkheim that suggests a commonality between Gilbert's approach and that of Durkheim.) These thinkers all emphasized in one way or another that people engaged in joint action were unified in a significant sense. Economists have begun to move beyond individual choice to investigate what has been called 'team reasoning' (see Bacharach, 2006).

Joint Attention during Infancy and Early Childhood Across Cultures

Jessica L Kinard and Linda R Watson, The University of North Carolina at Chapel Hill, Chapel Hill, NC, USA

Abstract

This article provides an overview of joint attention development. Typical development of joint attention is discussed, followed by joint attention in special populations. Finally, the influence of diverse cultures on joint attention is explored.

Introduction

"Look!" says Ellie, pointing to a seagull. She glances to her mother and then back at the bird.

"Wow, a seagull," says Ellie's mother. "And look! A kite!" She points to the sky and Ellie looks in the same direction, laughing as the kite swoops overhead.

In this interaction, Ellie is demonstrating an important skill, known as 'joint attention.' Joint attention is defined as coordinating attention between a referent and another person, in order to share interest in the referent (Bakeman and Adamson, 1984; Crais et al., 2004). To engage in joint attention, a child needs to either (1) direct someone's attention to a referent (i.e., 'initiation of joint attention') (Crais et al., 2004) or (2) respond when another person directs his/her attention to a referent (i.e., 'response to joint attention') (Mundy et al., 2007). In other words, joint attention interactions include three main components: (1) person A (e.g., the child), (2) a referent (e.g., an object, person, or event), and (3) person B (e.g., an adult or another child). Because joint attention involves these three components, it is sometimes referred to as a triadic interaction (Shin, 2012).

Initiating and responding to joint attention is a complex skill, crucial for infancy and early child development. In this article, joint attention is discussed in the following contexts: (1) typical development, (2) development in special populations, and (3) the influence of diverse cultures on joint attention.

Joint Attention in Typically Developing Children

This section discusses the milestones for joint attention development, types of communicative behaviors associated with joint attention, and relationships between joint attention and other developmental domains.

The nature of joint attention can be clarified by comparing it to other functions of communication. In early development, infants typically communicate for three main reasons, or 'communicative functions': (1) to influence another person's behavior in order to request or protest (i.e., behavioral regulation); (2) to draw attention to self for social purposes, such as during social games (i.e., social interaction); and (3) to draw attention to a referent, in order to share interest in the referent (i.e., joint attention) (Bruner, 1981; Crais et al., 2004). Behavioral regulation may occur as a dyadic (i.e., involving the child and another person) or triadic (i.e., involving the child, another person, and a third referent) interaction. In contrast, joint attention always involves three components; the child needs to establish a joint focus of attention on a referent outside of the dyad. Infants first communicate for behavioral regulation and social interaction; afterward, they begin to communicate for joint attention (Crais, 2011; Crais et al., 2004). Infants begin to develop joint attention around 7–10 months of age and have full joint attention skills between 12 and 18 months of age (Crais et al., 2004; Salley and Dixon, 2007).

Infants communicate to establish joint attention through a variety of communicative behaviors, or 'communicative means,' which could include gestures, eye gaze, vocalizations, and words. When developing ways of communicating, infants first use eye gaze and/or eye gaze combined with vocalizations, followed later by gestures and eventually words. Gestures tend to emerge without vocalizations, and then are combined with vocalizations shortly afterward (Crais et al., 2004). Some gestures are used exclusively for joint attention (e.g., showing an object to someone to share interest), whereas other gestures may be used to communicate for joint attention, as well as other purposes (e.g., pointing at an object to share interest, or pointing at an object to request).

Response to and initiation of joint attention both uniquely contribute to later language development, suggesting that both facets of joint attention play important roles in children's learning (Mundy et al., 2007). In the first 2 years of life, pointing and following another person's point, in particular, are important joint attention milestones (Colonnesi et al., 2010; Vallotton and Ayoub, 2010). Pointing is not the only way to initiate joint attention, nor is pointing restricted to the function of joint attention; however, this gesture is frequently used by young children and, thus, the literature on pointing may be especially relevant to the topic of joint attention.

Pointing and understanding others' pointing is strongly associated with the following skills, particularly when the pointing is for joint attention: (1) current language skills (i.e., in the first 2 years of life) and later developing language skills, including vocabulary related to cognition (e.g., 'think'), and (2) the ability to interpret another person's intentions later on (Colonnesi et al., 2010; Kristen et al., 2011; Mundy et al., 2007). Children can also use joint-attention-pointing as a tool for learning social emotional concepts, even after they learn how to talk (Vallotton and Ayoub, 2010). This literature suggests that both the function and form of joint attention play important roles in early child development.

Since pointing is an important gesture for joint attention development, a discussion of its development is warranted.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.23172-3

Researchers suggest that pointing develops gradually, first with an open-hand point and followed by an index-finger point (Liszkowski and Tomasello, 2011). Children who point with an index finger often demonstrate more communicative abilities than children who point with their whole hand. When compared to whole-hand pointers, children who point with an index finger tend to display the following behaviors: (1) pointing at referents more often, (2) combining vocalizations with their pointing more often, and (3) responding more appropriately to another person's point. In contrast, children who only point with their whole hand may look to where another person is pointing, but display less understanding of why the person is pointing to the referent, suggesting that children who point with an index finger have reached a higher stage of social cognitive development (Liszkowski and Tomasello, 2011).

Brain development research provides support for the relationship between pointing and cognition. Responding to joint attention may be associated with posterior attention systems of the brain, allowing children to reflexively respond to another person's bid for joint attention, whereas initiating joint attention may be associated with frontal attention systems in the brain, such as the anterior cingulate cortex, allowing children to understand their own and others' reasons for communicating (Hopkins and Taglialatela, 2013; Mundy et al., 2007). The posterior, reflexive systems are established early on, whereas the anterior, intentional systems are established later in infancy (Mundy et al., 2007). Based on this information, it seems reasonable that how children use pointing for joint attention could provide clues to their brain development.

Despite these linguistic and cognitive benefits, joint attention is not always associated with development of later skills. After children are about 2 years old, joint attention is not as predictive of how well children will learn vocabulary and grammar, perhaps because most children have gained joint attention by that time, and so joint attention is less able to differentiate between children who go on to develop higher or lower language skills (Salley and Dixon, 2007). Also, unlike the ability to follow a point, following another person's gaze is not associated with the ability to interpret that person's intentions; this difference may be because pointing is more salient to infants as a form of communication (Kristen et al., 2011).

In the first 2 years of life, however, joint attention predicts aspects of later development (Colonnesi et al., 2010; Kristen et al., 2011; Mundy et al., 2007; Vallotton and Ayoub, 2010). The child's use of more pointing may result in more joint attention with an adult, and thus, more verbal input to the child about a topic (Colonnesi et al., 2010; Goldin-Meadow et al., 2007; Vallotton and Ayoub, 2010). As adults respond to the child's focus, these interactions may help the child develop language (Goldin-Meadow et al., 2007) and social emotional understanding (Vallotton and Ayoub, 2010).

Although joint attention may promote language acquisition, the reverse may also be true: language skills could help children develop their joint attention. The diversity of a child's vocabulary may influence how well the child engages in joint attention with others, perhaps because a greater vocabulary can help children share more experiences (Vallotton and Ayoub, 2010). Children begin to develop their expressive vocabulary around 12–15 months of age (Mundy et al., 2007). Between 14 and 36 months of age, children continue to solidify their verbal and gestural behaviors, and become more adept at using them to interact with their parents (Vallotton and Ayoub, 2010). Children between 15 and 20 months, in particular, begin combining pointing and language, as their vocabulary increases and they begin putting words together (Colonnesi et al., 2010). Thus, although pointing is an important gesture prior to 1 year of age, it develops even stronger associations with language in the second year of life.

Children follow a general pattern of joint attention development, but their development may vary according to their communicative environment. The following variables could influence development of joint attention: (1) child temperament, (2) child gender, (3) maternal behaviors, and (4) the people involved in the interaction (Benigno et al., 2007; Crais et al., 2004; Mundy et al., 2007; Salley and Dixon, 2007; Shin, 2012).

In terms of temperament, toddlers who display more frequent negative feelings, such as fear and discomfort, tend to have lower language skills, point less often, and initiate joint attention less often; in contrast, toddlers who display more frequent positive affect, such as pleasure, tend to have higher language abilities. Possibly toddlers experiencing negative emotions focus on regulating their feelings more than paying attention to their environment, and thus have more difficulty developing joint attention and language skills (Salley and Dixon, 2007).

Regarding gender, 9-month-old girls initiate joint attention with eye contact more often than their male peers. This gender difference is not specific to joint attention, however, as girls from 9 to 24 months of age also initiate behavioral regulation more often than boys of similar ages (Mundy et al., 2007). These differences in early prelinguistic communication of joint attention and behavior regulation may give girls an advantage in developing language skills at an earlier age than boys.

Finally, the people involved in the interaction may influence the child's joint attention development. When parents engage their children socially and emotionally, these interactions foster imitation, joint attention, and conversational skills. Researchers argue that this social emotional engagement supports the later development of joint attention skills, allowing children to practice paying attention to another person before paying attention to both their play partner and a shared referent (Farrant et al., 2011).

More joint play tends to occur when toddlers are engaged in a one-to-one interaction with a parent, as opposed to a parent–child–sibling interaction. However, when an older sibling joins the play, the toddler and parent demonstrate more joint attention with each other than in the one-to-one situation, suggesting that toddlers are capable of establishing joint attention even when both, they and their sibling, are vying for their parent's attention. Furthermore, toddlers demonstrate larger vocabularies when they establish joint attention in a parent–child–sibling interaction, as opposed to one-to-one situations with a parent. In parent–child–sibling contexts, the siblings establish joint attention more often with their parent than with each other (Benigno et al., 2007).

Some researchers speculate that infants do not actually point for joint attention, but for behavioral regulation (Southgate et al., 2007), an idea that would be supported by

findings that infants do not use pointing with other children, only with adults who are more capable of meeting the infants' behavioral regulation demands. However, Shin (2012) examined social communication skills in 9- to 23-month-old children in a child care setting, and determined that, in addition to regulating each other's behavior, children also communicated with each other for purely joint attention purposes. Therefore, children do appear to communicate with each other simply to share interest in referents. Joint attention between infants and toddlers appears to be an important way for children to develop social cognition and play skills (Shin, 2012).

Joint Attention in Children with Special Needs

Some disorders change the developmental trajectory of joint attention. In this section, joint attention in the following conditions will be discussed: autism spectrum disorder (ASD), Down syndrome (DS), Williams syndrome (WS), blindness, and deafness.

Autism Spectrum Disorder

Joint attention deficits are key impairments in children with ASD. According to the fifth edition of the Diagnostic and Statistical Manual of Mental Disorders, ASD is characterized by deficits in two main areas: (1) social communication and social interaction and (2) restricted, repetitive patterns of behavior, interests, or activities (Paul and Norbury, 2012). Deficits in social communication and social interaction could impact the following areas: back-and-forth social interactions, understanding and using nonverbal communication, and/or starting and keeping social relationships. The category of restricted and repetitive behaviors includes the following areas: repetitive speech, movements, or interactions with objects; insistence on following routines and resistance to change; obsessive interests or fixations; and unusual reactions to sensory stimuli in the environment.

Based on these criteria, it seems logical that children with ASD would struggle with joint attention. First, joint attention is highly dependent on understanding and producing nonverbal communication, particularly when infants are first developing joint attention skills (Crais et al., 2004); however, nonverbal communication is often a deficit in children with ASD (Mundy et al., 1986; Paul and Norbury, 2012). Second, joint attention involves sharing interest in a referent with another person (Crais et al., 2004); however, children with ASD struggle with social interactions (Adamson et al., 2009; Paul and Norbury, 2012). Poor social motivation to share interests with another person may contribute, at least partially, to difficulties with joint attention skills in children with ASD.

Finally, restricted and repetitive behaviors could also disrupt joint attention development. If children with ASD fixate on obsessive interests and have difficulty with change, it will likely be difficult for them to switch their attention between a referent and another person, whether to initiate or respond to joint attention (Adamson et al., 2009; Mundy et al., 2007; Paul and Norbury, 2012). Unusual sensory reactions may also hinder joint attention development; for example, if children are undersensitive to stimuli, then they may not respond easily when someone tries to gain their attention (Paul and Norbury, 2012). It is interesting to note that, although children with ASD have relatively strong behavioral regulation skills, they tend to struggle with 'triadic' behavioral regulation (e.g., switching attention between a referent and another person to request help) more than with 'dyadic' behavioral regulation (e.g., paying attention to only one entity to request) (Phillips et al., 1995; Watson et al., 2013). These difficulties with triadic behavioral regulation suggest that, in addition to social motivation, the triadic nature of joint attention could be a factor that makes joint attention difficult for children with ASD.

Supporting these ideas, a wealth of research exists on the development of social communication in children with ASD. The minimal use of joint attention gestures is what consistently distinguishes children with ASD from other children, both those with typical development and those with other developmental disabilities (Adamson et al., 2009; Paparella et al., 2011; Watson et al., 2013). Infants and young children with ASD are less likely to communicate for joint attention purposes when compared to other children, even when children with ASD have a large expressive vocabulary (Adamson et al., 2009; Watson et al., 2013). For example, typically developing children and children with non-ASD disabilities markedly increase their use of joint attention gestures over the 9- to 18-month age range; conversely, children with ASD have a relatively flat trajectory of joint attention development (Watson et al., 2013) and continue to have difficulties with joint attention at preschool age (Adamson et al., 2009). Gestures associated with joint attention seem to be difficult for children with ASD to learn, such as following another person's gaze, showing referents, and pointing (Paparella et al., 2011). It is important to note that, even though children with ASD clearly struggle with joint attention skills, some infants later diagnosed with ASD communicate for joint attention purposes, even at very young ages (Paparella et al., 2011).

As with typically developing children, joint attention skills of children with ASD may vary according to their background. Caregivers can play a large role in how well children with ASD learn joint attention skills. Parents of children with ASD do not appear to differ from parents of other children, in terms of how much they follow their child's lead or direct their child's behavior (Siller and Sigman, 2002; Watson, 1998); however, a highly responsive caregiving style (i.e., following the child's lead, rather than requiring that the child switch his/her attention) is even more strongly associated with later social communication gains in children with ASD (Siller and Sigman, 2002, 2008) than in typically developing children (Landry et al., 2001; Tamis-LeMonda et al., 2001). This type of parenting style may be particularly important for children with ASD, given their difficulties with joint attention.

Down Syndrome

DS is a genetic condition, which, in most cases, results from an extra copy of chromosome 21. Children with DS exhibit characteristic physical traits, such as low muscle tone, large tongue, fold of skin on the eyelid, and small height. Children with DS also demonstrate delays in many areas of development, such as cognition, motor skills, and receptive and expressive language (Paul and Norbury, 2012).

Despite difficulties with language, social communication appears to be a strength for children with DS (Adamson et al., 2009). Children with DS tend to develop joint attention more slowly than typically developing children, but in a similar developmental progression (John and Mervis, 2010). Compared to 18- and 30-month-old typically developing children, 30-month-old children with DS can often maintain joint attention at similar levels (Adamson et al., 2009). Preschoolers with DS can also frequently tell the difference between communicative gestures and actions that look like gestures, but are noncommunicative (e.g., pointing with an index finger versus holding out a finger, but not actively pointing at anything) (John and Mervis, 2010). Children with DS can often find hidden objects when an adult gestures toward the object, indicating an ability to understand others' gestures, even when the children with DS have low cognitive and language skills (John and Mervis, 2010). As with typically developing children and children with ASD, children with DS tend to have difficulty following another person's gaze and understanding what the gaze means; pointing combined with eye gaze appears to be an easier gesture to understand (John and Mervis, 2010; Kristen et al., 2011; Paparella et al., 2011). Despite their overall abilities to engage in joint attention, children with DS have more difficulty than children with ASD at producing expressive language, even after 30 months of age (Adamson et al., 2009).

Williams Syndrome

WS is a genetic condition that occurs when about 25 genes are deleted from chromosome 7q11.23. Children with WS demonstrate characteristic physical features, such as a small chin and upturned nose, and characteristic behaviors, such as being overly friendly and anxious. Children with WS also demonstrate delays in many domains, such as visual-spatial difficulties, nonverbal delays, and intellectual disabilities; however, some children with WS have intellectual abilities in the low normal range (Paul and Norbury, 2012).

Similar to children with DS, children with WS can often tell the difference between a communicative and noncommunicative gesture. Unlike children with DS, most children with WS have difficulty finding hidden objects when an adult gestures toward the object, suggesting that understanding these gestures is a challenge. Not surprisingly, children with WS struggle to interpret another person's eye gaze and have an easier time following pointing. Overall, children with WS demonstrate relatively strong language skills and motivation for social interaction; however, they struggle with social communication skills, like understanding and producing joint attention gestures. Therefore, children with WS and DS each have unique profiles: children with WS demonstrate strengths in language and difficulties with joint attention, whereas children with DS struggle with language, but have relatively strong joint attention (John and Mervis, 2010).

Blindness

Children who are blind from birth may have early difficulties learning language, but typically catch up by the time they enter school (Paul and Norbury, 2012). Joint attention skills, on the other hand, are more challenging for these youngsters. For many congenitally blind children, early social communication may appear similar to children with ASD, although there are many differences between the two conditions (Bigelow, 2003; Brown et al., 1997; Hobson et al., 1999). Children who are blind tend to demonstrate more typical social affect and more instances of pretend play than sighted children with ASD, even if the children who are blind demonstrate other characteristics of ASD (Hobson et al., 1999).

It is easy to imagine why joint attention would be difficult for children who have visual impairments. Typically developing children largely rely on vision to coordinate their attention between a person and a referent, both to see what another person is referring to and to direct another person's attention (Crais et al., 2004). Children who are blind cannot rely on vision for joint attention, but instead must rely on other means, such as touch, hearing, and memory of spatial orientations (Bigelow, 2003). These alternate means may be difficult for some blind children to learn, such as children with cognitive impairments; thus, blind children with cognitive impairments may display more ASD-like characteristics than blind children without additional deficits (Brown et al., 1997).

Cognitive skills are highly involved in developing non-visually based joint attention. For children who are blind, a stepping stone to joint attention is the development of object permanence. These infants must first understand that objects exist and can be physically manipulated, before they can learn to coordinate their attention between objects and another person. Infants may demonstrate understanding of object permanence by actively searching for objects and by using another person as a tool for finding those objects. For example, an infant might feel along a person's arm to locate the object in his/her hand, but not actively communicate with the other person to share interest in the object. Infants who are blind might also engage in self-stimulating behaviors, such as head shaking, which parents can help shape into communicative behaviors, like shaking head for 'no' at around 18 months. These self-stimulating behaviors tend to decrease as children are better able to control their surroundings (Bigelow, 2003).

As children who are blind learn words, they start to use those words to label objects and follow verbal instructions, indicating a growing understanding of objects in their surroundings (Bigelow, 2003). Early response to joint attention can be seen when a child and a parent are playing with an object together, but the child fusses when the parent stops playing. However, even once object permanence and social interactions are established, initiating joint attention is often difficult for children who are blind, since they cannot see what is available in their environment. Once they begin to establish a vocabulary, children who are blind can more easily respond to and initiate joint attention; however, they continue to have difficulty initiating joint attention about distant objects and abstract concepts. Communication partners can provide context clues to help children who are blind perceive their environment and focus their attention (Bigelow, 2003), perhaps helping to reduce ASD-like symptoms (Hobson et al., 1999). Therefore, although joint attention is important for developing language skills, the reverse is also true: language

skills are important for developing joint attention, particularly for children who are blind (Bigelow, 2003).

Deafness

Children with severe to profound hearing impairments demonstrate a range of language and social communicative abilities. The language environment in which children grow up plays a large role in how they learn to communicate, such as whether they are born to parents who are deaf or with typical hearing. The communicative styles of these parents are highly variable, which could impact how children learn to engage in joint attention (Gale and Schick, 2009; Paul and Norbury, 2012).

Regarding both oral and signed communication, deaf 2-year-olds with deaf parents tend to engage in less joint attention using words than hearing 2-year-olds with hearing parents. This difference may be because, when using sign language, deaf children need to split their attention between looking at another person's signs and looking at the object, whereas hearing children can simultaneously look at and communicate about the object. Also, deaf children may need more time to visually explore objects before they can communicate about them. Among deaf 2-year-olds of hearing parents, toddlers tend to use more words (including both oral and signed vocabulary) during joint attention than deaf children of deaf parents, but fewer words than hearing children of hearing parents (Gale and Schick, 2009).

Despite these differences in word use during joint attention, deaf 2-year-olds with deaf parents tend to have similar expressive vocabularies as hearing children with hearing parents, when both sign and oral vocabularies are included in the count. This suggests that the deaf toddlers of deaf parents are not necessarily at a disadvantage for learning language within joint attention routines, simply because they use less words than hearing children in these routines; rather, deaf toddlers may simply need more time to look back and forth between the referent and adult when communicating. On the other hand, deaf 2-year-olds with hearing parents tend to have much lower expressive vocabularies (including both oral and signed vocabulary) than hearing children with hearing parents (Gale and Schick, 2009).

A possible explanation for these differences is that deaf parents may be more sensitive to their deaf child's need to visually explore objects, giving them more time to process information, whereas hearing parents tend to engage their children in several, short interactions about an object, rather than maintaining attention on one topic (Gale and Schick, 2009). Deaf parents also tend to use tactile cues, such as tapping the child to gain his/her attention, before signing words (Akhtar and Gernsbacher, 2008). Another possible explanation for these vocabulary differences relates to the parents' linguistic fluency. Deaf parents are likely to be fluent in sign language, and so could provide rich vocabulary models for their children; on the other hand, hearing parents may be beginning learners of sign language, and so might not provide as many vocabulary models for their children (Paul and Norbury, 2012). Furthermore, although hearing parents may have rich oral vocabularies, their child's hearing impairment prevents the child from fully accessing this information. These styles of interaction may influence how many words a toddler is able to process and learn within joint attention routines.

Joint Attention in Diverse Cultures

In this section, the influence of diverse cultural backgrounds on joint attention will be considered, both in relation to typical development and development of children with special needs.

In general, infants from diverse cultures demonstrate similar social communication skills as infants in the United States (Blake et al., 2005; Callaghan et al., 2011; Childers et al., 2007; Salomo and Liszkowski, 2013). For example, as Japanese and Italian-Canadian infants approach 14 months, they tend to increase their joint attention gestures (Blake et al., 2003, 2005). In Nigeria, infants also tend to increase the complexity of their joint attention from 1 to 2 years of age (Childers et al., 2007). These joint attention interactions seem to be important for later receptive language development in both Japanese and Italian-Canadian infants (Blake et al., 2003) and expressive language development in Nigerian toddlers (Childers et al., 2007), similar to studies of children in the United States (Mundy et al., 2007). Infants from the Netherlands, China, and Mexico also demonstrate joint attention gestures at 11 months of age, such as pointing, showing, and offering objects to establish joint attention (Salomo and Liszkowski, 2013). Somewhat differently from these groups, French infants tend to increase their joint attention up to about 11.5 months of age, and then reduce their frequency of joint attention, while infants who are English-Canadian tend to have high levels of joint attention gestures throughout the 9- to 14-month age range (Blake et al., 2005).

Regarding response to joint attention, infants from Canada, Peru, and India are able to respond to joint attention bids at a similar rate, including both (1) following a point to an interesting picture from 8 to 13 months of age and (2) following gaze to find hidden objects at 12 months of age. However, infants from Canada show somewhat more success at finding hidden objects than the infants from Peru and India, perhaps because the Canadian infants have more opportunities to move around independently (Callaghan et al., 2011).

Despite these similarities, differences in joint attention and related aspects of social communication also exist across cultures. Some of these differences may relate to the amount of time that infants spend in social interaction. For example, infants in China may have more opportunities for interaction than Dutch infants in the Netherlands, and so Chinese infants tend to point more often; along similar lines, Dutch infants may have more opportunities for interaction than Mayan infants in Mexico, and so, in turn, Dutch infants tend to point more often than Mayan infants (Salomo and Liszkowski, 2013). Parent education may play a role in how children from different cultures develop gestures. In a study of 12-month-olds from India, Canada, and Peru, Indian infants pointed for joint attention significantly less often than Canadian infants, while Peruvian infants pointed at a rate somewhere in the middle, not significantly different from either the Canadian or Indian infants (Callaghan et al., 2011). The authors proposed these differences may relate to

maternal education, rather than cultural differences per se, since the mothers from India had lower education than the other two groups.

The use of eye gaze, so important in Western cultures in establishing joint attention, is another behavior that varies across cultures (Akhtar and Gernsbacher, 2008). For example, from 9 to 14 months, Japanese infants may not increase how frequently they coordinate eye contact with other gestures for communication, indicating that, despite the importance of eye contact in English-speaking cultures, it may not be as significant in Japanese social communication (Blake et al., 2003). Additionally, mothers in Kenya tend use less eye contact with their infants than mothers in the United States, instead focusing on interactions that involve touch and holding the child close. Families in Papua New Guinea and in Palestine tend to hold their infants facing outward, rather than inward, making eye contact more difficult to establish and changes in head motions more difficult to notice. Therefore, tactile and verbal means of communication may be more relevant in these cultures than visual communicative means, and could potentially function in the same role as eye gaze (Akhtar and Gernsbacher, 2008). The use of touch is particularly important for developing joint attention of infants who are blind, as well as infants who are deaf, so it seems logical that tactile cues could also be important for joint attention in other cultures (Akhtar and Gernsbacher, 2008).

In summary, infants from diverse cultures demonstrate both similarities and differences in joint attention development. An interesting consideration is whether diverse culture plays a role in the joint attention of children with disabilities. Research on this topic is rare, but a study was recently completed in the United States, comparing the communication of monolingual and bilingual toddlers with ASD (Valicenti-McDermott et al., 2013). Although the bilingual English-Spanish-speaking toddlers demonstrated more cooing, gesturing for behavior regulation, and simple pretend play than the monolingual English-speaking toddlers, the groups were similar in their use of social interaction gestures (e.g., waving goodbye) and joint attention gestures (e.g., showing objects). Based on these findings, it appears that learning two languages does not impair the joint attention development of children with ASD, and may be associated with benefits in other aspects of communication development.

Conclusion

Joint attention is a social communication ability that develops early in infancy and progresses throughout early childhood, allowing children to coordinate their gaze between a referent and another person, in order to share interest in that referent. In early development, communicating for the purposes of behavioral regulation and social interaction generally precedes communicating to establish joint attention, and the acquisition of these two communicative functions may help form the foundation for joint attention. Although development varies based on individual differences, children progress through a typical hierarchy of social communication development, allowing them to solidify their joint attention skills through use of gestures, eye gaze, vocalizations, and words. In turn, these joint attention skills are related to concurrent and longitudinal gains across many developmental areas, such as language, social cognition, social emotional understanding, and joint play.

Developmental and physical disabilities may disrupt this typical progression, making it difficult for children to acquire joint attention. Overall, infants and toddlers from diverse cultures demonstrate similar joint attention skills; however, some cultural differences in joint attention do exist. Cultural differences may also influence how social communication symptoms are presented in children with disabilities.

Journalism

Daniel C Hallin, University of California, San Diego, La Jolla, CA, USA

Abstract

Journalism refers to the activity of gathering and presenting news for public dissemination. It has played a central role in modern society as a political institution, a business, and a form of popular culture. It has taken many forms in different historical periods and political and economic contexts, varying, for example, in its relation to political institutions, its status as a profit-making business, and the degree to which it is 'professionalized'.

Journalism is generally defined as the activity of gathering and presenting information and commentary about current events for public distribution. From a social science point of view, it can be conceived in a number of ways: as a distinct occupation with its own patterns of recruitment and socialization and occupational subculture; as a distinct form of social activity involving the gathering and processing of information; as a social institution with a set of relations with other institutions like the state; or as a cultural form or form of discourse.

Disputes about the boundaries of journalism have been common, among both scholars and practitioners. Chalaby (1998), for example, has argued that journalism properly so-called emerged in Britain and the United States with the development of commercial mass media; the production of news as a commodity, in his view, is radically distinct from the earlier practice of using the press to publicize political ideas. Journalists' organizations, particularly in countries with state-owned broadcasting systems, have sometimes excluded those who worked in broadcast news, on the grounds that they did not practice journalism independently, but merely transmitted the views of others. In many countries today there is debate about whether independent Internet 'bloggers' or those who produce new forms of 'infotainment' like talk-show hosts can legitimately be called journalists. There is little to be gained conceptually by trying to adjudicate these disputes and establish the 'true boundaries' of journalism. These disputes are enlightening precisely because multiple forms of journalism have always coexisted, and because journalism has never been rigidly differentiated from other social activities, but has overlapped with and existed in relations of mutual interdependence with a variety of political, economic, social, and cultural institutions and practices.

Historical Evolution

The term 'journalist' emerged in the seventeenth century; originally, 'journalism' referred simply to the activity of producing a printed periodical. One can trace many of the social functions involved in journalism to earlier eras, but it seems best to say that journalism emerged with the development of the newspaper and other forms of print culture. The emergence of journalism was connected not only with the development of print technology, but also with an interrelated set of social and cultural changes. First, it was connected with the development of capitalism and the market. This was true in two senses. The market, first of all, increased the demand for specialized sources of information. Those involved in market relationships had an intensified need to know about occurrences beyond their own world of face-to-face relationships. Merchants were among the first producers and consumers of newspapers, and as increasing parts of the population were drawn into the market economy, newspaper readerships grew. Second, newspapers were themselves distributed through the market, and in many countries newspapers were among the first mass-produced consumer commodities. This is not true in all cases, however. Party newspapers in Europe, for example, were often distributed through party-related organizations, and newspapers in Communist systems also distributed through organizations and in workplaces.

Second, the emergence of journalism was connected with the rise of the nation-state and political citizenship. It is connected of course with the emergence of democratic politics; early newspapers were often primarily vehicles for public political participation. Expansions of newspaper readership were often closely connected with expansions of the electoral franchise. In the United States, for example, the rise of the 'penny papers', which greatly expanded the audience for news, came on the heels of the Jacksonian revolution and the elimination of property qualifications for voting. In Uruguay, one of the few Latin American countries in which a mass circulation press has developed, newspaper circulations increased from 1 newspaper for every 11 inhabitants in 1870 to 1 for every 4 in 1916, a period that also saw the rise of mass-based political parties.

The notion of citizenship is broader than that of democracy, however, and the connection between journalism and the rise of the nation-state goes beyond the development of democratic political institutions. Another way in which the modern nation-state draws the mass public into political life is through mobilization for war; newspaper circulations have typically expanded in times of war as well as in times of expanded political participation. As Anderson (1991) has pointed out, the culture of nationalism involves a sense of belonging to an imagined community of compatriots; journalism is one of the key cultural forms in the creation of this sense of national collectivity, and it can play this role with or without political democracy.

Finally, journalism is connected with the rise of realism as a cultural form; it emerges simultaneously with a number of

related realist genres, including the novel and scientific writing, and indeed has in certain historical periods overlapped with these, as novels and scientific information were published in newspapers and novelists often wrote for the press. All three of these historical changes are connected with the rise of the 'public sphere'.

Max Weber (1946) once characterized the journalist as a 'type of professional politician'. And indeed in its early days journalism was substantially – though not exclusively – a part of the world of politics. Journalists were often advocates for political causes; Benjamin Franklin, for example, who like many others in his age was simultaneously a journalist and a politician, described journalism as essentially a form of oratory and thus part of a tradition that could be traced back to the political assemblies of Greece and Rome. In democratic countries, newspapers typically became associated with political parties, as these began to emerge, or factions of parties, and often were supported financially by parties or individual politicians. In authoritarian countries, newspapers were often political mouthpieces of either the state or insurgent movements. In Africa, for example, many leaders of the independence movements of the twentieth century were involved in journalism.

The identification between journalism and politics was substantially changed, however, by rise of a commercial newspaper industry. This began in the Unites States in the 1830s, with the development of the 'penny papers', which expanded newspaper circulations by an order of magnitude and became profitable cultural industries by selling the attention of a mass audience to advertisers (Schudson, 1978). In Britain, commercialization of the press was delayed by restrictive taxes, but got under way in the 1850s. In Japan, similarly, commercial papers began to compete with the earlier, politically oriented papers at the end of the 1870s. Commercialization did not push politics aside altogether. Most newspapers in the United States, for example, continued to have strong partisan loyalties throughout the nineteenth century, and their owners and editors to be active in politics. They were, however, financially independent of parties, and their owners were independent political powers in a way their predecessors often had not been. In this sense, it could be said that commercialization increased the power of journalism as an institution. Commercialization also changed the agenda and style of journalism, diminishing political advocacy in favor of the competition to provide news in a timely and sometimes sensational fashion.

A sharp debate has emerged in media studies over the implications of commercialization of the news media for democratic politics. One view holds that commercialization gives the press the independence it needs to serve as a 'watchdog' of the state and to provide the public as a whole with information 'without fear or favor'. The contrary view holds that commercialization tends to drive political content out of the press, replacing it with sensational human interest material, and also to consolidate control of the press in the hands of the upper class, leading to unequal political competition between competing social interests (Curran and Seaton, 1997). This argument has been developed especially from the case of Britain, where a highly politicized working-class press flourished in the period when taxes inhibited the development of commercial media. Weber (1946) also observed that the commercial papers in Germany "have been regularly and typically the breeders of political indifference".

Commercial newspapers were the first to employ hired reporters, editors, and eventually artists, photographers, and other specialized journalistic personnel. Throughout the nineteenth century, journalism developed as a distinct occupation with specialized practices and a sense of identity. Many of the conventions for gathering and presenting information, which we now think of as distinctively journalistic, emerged in these years, including the summary lead, which synthesizes the 'most important' information in a news story for the reader, and the practice of interviewing public figures, which was important in part because it gave journalists a more active role in the creation of news, and in some cases increased the public profile of individual journalists.

In the twentieth century, the notion of journalism as a 'profession' began to emerge, most distinctively, perhaps, in the United States, where the idea of neutral expertise became a particularly strong element of political culture. Professionalization meant, above all, the development of the idea that the journalist serves the public as a whole, rather than particular political tendencies, owners, or other interests. It is associated with the shift, noted by Siebert et al. (1956), from the older 'libertarian' conception of press freedom to the 'social responsibility' model, which sees the press as the holder of a public trust. Professionalization was also associated with a shift toward balance and 'objectivity' as primary journalistic values (though more strongly in the United States, than in many other countries), and with increased autonomy of journalists, as against owners or managers, within news organizations. Journalistic autonomy has nevertheless always been limited: despite aspirations in some countries for direct journalistic control of news organizations (perhaps most notably France after World War II; the journalists at *Le Monde* once controlled and still participate in the election of the director), ultimate authority in virtually all news organizations remains outside the hands of journalists.

Several decades of scholarship have painted a complex picture of the implications of the professionalization of journalism. Professional norms can be seen, for example, both as a mechanism of social control, constraining journalists and often serving to exclude nonconforming content from the news, and as a basis for journalists' autonomy, legitimizing their right to a space of action not constrained by their owner's political views, the pressures of advertisers, etc. The concept of professional routines has become central to the analysis of the social role of journalism. Routines are the standard practices that enable news organizations to operate efficiently and that legitimate the many choices that must be made in the production of news, allowing them to be treated as matters of shared professional judgment rather than of political debate. Where professionalism is strong, these routines are powerful enough that particular individuals, including both journalists and owners, have limited ability most of the time to shape news content. These routines, however, often have social biases built into them, and most scholars consider the biases built into journalistic routines to be the most important explanation for the politics of news (Schudson, 2003). Among the most important routines is the use of certain kinds of sources of

information that are considered 'authoritative' – principally government officials and other elite members of society (Gans, 1979; Hall et al., 1978).

There are many views about what kinds of social 'biases' prevail in contemporary journalism. Some, for example, have argued that journalism generally undermines the authority of established social institutions (this view began to grow in the 1970s, which probably saw the high point of journalistic autonomy in most Western countries, and also a decline in the legitimacy of many social institutions). Some have argued that they serve more or less consistently to support established social interests, and others that they are essentially neutral, and represent the full range of contending interests. The most common view among scholars is probably that in liberal societies media routines tend to reproduce the existing structure of power, but not in an entirely consistent way; under certain circumstances, for example, the dominant routines can open the media to penetration by new social movements or lead to periods of contestation over the boundaries of political debate.

Differentiation

Structural functionalism holds that human societies tend to evolve toward increased differentiation, in which institutions become increasingly specialized in the functions they perform. Some scholars – most notably Alexander (1981) – have argued that the development of journalism should be seen in this light. This does make considerable sense in societies where commercialization and professionalization are relatively advanced. Journalism in these societies has increasingly become separated from party politics, and has developed norms and routines of its own, a 'media logic' distinct from the logic of politics. In other ways, however, the notion that journalism tends to evolve toward differentiation seems doubtful. Most importantly, such a view neglects the tendency for journalism to become integrated into market mechanisms. Professionalization, to be sure, limits this to some degree, but the 'media logic' that has emerged in contemporary societies is very much a joint product of professional norms and the pressures of the market, which many argue are growing increasingly strong. Other scholars thus give a very different account of the history of journalism than the structural functionalists. Habermas, for example, decries the 'colonization' of the public sphere by the cultural industries, and Bourdieu argues that the journalistic field once heavily influenced by the political field is now heavily influenced by that of the market.

Journalism and the State

In liberal societies, journalism is generally thought of as standing apart from the state, serving to check its power as a watchdog or the fourth estate. This is accurate to a significant degree, as reflected in incidents like the publication by *The New York Times* and other papers of the 'Pentagon Papers' (a secret government study of US decision making on the Vietnam War 'leaked' to the press by a dissident former official). But close ties between the media and the state also exist in liberal societies. State subsidies and restraints do exist in such societies, as do clientelist relationships between politicians and media owners. But more important is the close relationship between journalists and government officials as sources and subjects of news, respectively, a relationship that has proved mutually beneficial to officials seeking publicity and control over the news agenda, and to journalists seeking news. This relationship is highly developed, with the news media organizing much of the newsgathering process around the institutions of the state, and the state devoting considerable resources to accommodating them. In many cases, the relationship is formally organized, as in the lobby system in the British parliament or the press clubs of Japan. The closeness of the relationship between contemporary journalists and state officials means that journalists have access to considerably more information about the inner workings of government than they would have as outsiders. It also means that they are often in an important sense part of the community of political elites, and reflect the prevailing viewpoints within that community. Here, again, doubts can be raised about the differentiation theory of journalism history: it could be argued that journalism is more entangled with the state than it was a century or two ago, when journalists had no privileged access to the corridors of power.

In many political systems, the news media are much more directly integrated into the state, because either they are directly owned by state and party apparatuses, as in China, or few sources of capital exist to support news media outside of the state, as in some developing countries. In other cases, they will be tied more indirectly, through dependence on state advertising, for example, payments to journalists, or personal ties between owners and politicians.

Varieties of Journalism

Journalism has always been plural; indeed one of the distinctive characteristics of the modern newspaper is the fact that it mixes widely disparate types of content, not only in terms of subject matter, but also in terms of the functions it fulfills for readers. Journalism provides both information and entertainment. It also provides moral and ideological orientation. Even in countries where objectivity became a dominant professional value, there continue to be many occasions when journalists communicate value judgments to their readers, particularly when the society's consensus or hegemonic values are considered to be at stake, in covering international conflict, for example, or in investigative reporting. Some scholars have also argued that journalists perform a ritual function, promoting a sense of community solidarity, particularly in coverage of ceremonial events and crises.

In most societies, there is also some differentiation of journalism into distinct styles, often serving different parts of the community. One clear example is the differentiation of the British press between the 'quality' or broadsheet press, serving middle- and upper-class readers and emphasizing informational journalism, and the mass or tabloid press, serving primarily working-class readers with a much more entertainment-oriented form of journalism. In France, a distinction has often been drawn among 'rationalist', 'sensationalist', and 'ideological' newspapers, the latter including Catholic and Communist

organs. In many countries, local and regional papers are more commercially oriented and lack distinct political orientations, while national (or capital city) papers reflect distinct political tendencies. In the United States, ethnic minority media have played an important role, and often practice a form of journalism that was intended less to provide neutral information than to defend the interests of a particular part of the community.

Diverse social and political systems have also given rise to diverse forms of journalism. In Western Europe, newspapers tied directly or indirectly to political parties and other organized social groups like trade unions or churches remained important for most of the twentieth century, and the functions of journalism included much more emphasis on representing ideas and social interests in the public sphere as well as participating in the process of bargaining among groups, parties, and politicians, alongside the information and entertainment functions associated with commercial media. The party press has declined dramatically since the 1970s in Europe, but most newspapers in Southern Europe still have partisan identities and alliances, newspapers across the region continue to have more clearly differentiated political orientations than those in the United States, and European journalists are more likely to see commentary and to some degree advocacy as integral to the journalist's role than their US counterparts (Hallin and Mancini, 2004).

In many parts of the world, journalistic partisanship in one form or another is more the norm than the exception. Its form is often different from the party press of Western Europe, as the strongly institutionalized political party system of twentieth-century Europe is distinct from the political structures found elsewhere. In much of Asia, for example, the relation between media and politics is characterized by a fluid kind of partisanship based on shifting personal alliances, in which journalists both serve and participate in complex processes of maneuvering among political and economic power brokers. Rather than stable partisan alliances and identities, as one often finds with European news media, many Asian newspapers are characterized by what McCargo (2012) calls 'partisan polyvalence,' with different journalists at the same paper expressing the views of different actors with which they have ties. In many systems, journalism is very much an instrument by which particular actors – politicians, business people, leaders of ethnic groups or clans – pursue their economic and political interests; in this context, of course, the analysis of 'professional routines' referenced above, which is derived from the Western experience, is much less relevant to understanding the behavior of journalists or the content and role of the news media.

Journalism in Communist societies also evolved into distinct models that remain strong in countries like China and Vietnam. This model had its roots in the Western European tradition of party journalism, oriented toward political mobilization. But with the fusing of party and state, journalists became official figures and distinctive functions evolved. Journalism is an important institution in a Communist system, and news media are typically well supported by the state, trade unions, and other official institutions to which they are attached. Their functions are varied and complex, and include mobilizing people around the policy goals of the party-state, gathering social information for confidential dissemination within the political elite, serving as vehicles for debate among factions and ideological tendencies within the party and society, as well as serving a kind of ombudsman function, as an institution to which ordinary people could complain, hoping to be heard by those in power. In the Chinese case, the introduction of market mechanisms into parts of the Chinese media has introduced further complexity of different forms and functions of journalism, without changing its essential integration into the party-state (Zhao, 2012).

Current Developments

A number of powerful forces are currently transforming journalism and its social role.

Commercialization

In many countries, the news media have become increasingly commercialized and journalism more strongly influenced by market factors. In the West, the news media have been substantially commercialized since the nineteenth century. But for much of this century the effects of market forces on the news media have been partly counterbalanced by professionalization, public service broadcasting (which had a monopoly in Europe until the 1980s), and press subsidies, which many European countries expanded in the 1970s to keep politically oriented papers alive and prevent market forces from eliminating competing voices. These counterbalancing forces have been weakened in recent years, though public service broadcasting remains an important institution in much of Europe and some other parts of the world.

The culture of journalistic professionalism has been undermined in important ways by the shift to commercialism, and may also have been undercut by a general decline in the prestige of political life. A key element of that culture was the idea that journalists should make independent judgments about what citizens needed to know about public affairs. Today, it is increasingly assumed that it is the journalist's job to provide whatever content interests the media consumer. The news agenda has shifted away from public affairs in the traditional sense, and toward human interest and 'service' journalism useful to ordinary people in everyday life (investment advice, health reporting) (Hallin, 2000). Journalistic autonomy has been undercut in important ways, as the business and editorial sides of news organizations are increasingly integrated.

Some argue that these changes have made journalism less elitist, more responsive to the concerns of the majority of the population, and others that they undermine the integrity of the system of public communication. Journalism clearly has important functions for the society as a whole that most private industries do not have. It is central to political life, and to the process of opinion formation more generally; some have argued that it is increasingly central, as other institutions, political parties and trade unions, for example, have weakened. It remains one of the key questions of media studies whether market mechanisms can provide the fulfillment of these functions, and if not, what other social mechanisms can be devised.

The Economic 'Crisis of News'

In the United States and some other parts of the world, the economic model that underpinned the most important news media has been under strain for some time, and reached a point of crisis during the first global economic downturn of the twenty-first century. The number of newspapers has generally been declining in Western countries since the 1950s, and since the 1980s, many news organizations have cut back drastically on their staffs. The US television networks, for example, which once had foreign correspondents stationed around the world, now have virtually none, and most newspapers have cut the size of their reporting staffs dramatically, eliminating many specialized beats (arts and culture, for example) and much of their daily coverage of government, business, and other social institutions.

Emergence of New Forms of Partisanship and the Decline of 'Objectivity'

The party press, as noted above, declined in Western countries in the mid- to late twentieth century, this occurred particularly early and strongly in the United States. That trend has been partially reversed, however, as partisan media have been revived in the United States, and a shift has taken place from factual reporting of information to an emphasis on opinion, commentary, and satire, from forms of journalistic discourse that emphasize 'objectivity' to more 'subjective' ones (Baym, 2010). This change is associated with cultural shifts (from 'modernism' to 'postmodernism') and with an economic and technological shift from a highly centralized media environment where the monopoly newspaper and the government-regulated television networks were central to the multichannel media environments of radio, cable television, and the Internet. In the latter, many media target niche audiences distinguished by demographic category, lifestyle, and worldview, and partisanship is often an effective marketing device.

Democratization

In many developing and newly industrialized countries, there has been a move toward liberal democracy in recent years, with many authoritarian regimes giving way to multiparty systems and greater political openness. An increased emergence of independent news media has been associated with these changes, probably as both cause and effect. Opposition parties have increasingly gained access to the media in many countries, political scandals have proliferated (Waisbord, 2000), and elites have lost much of the tight control over public discourse they once held. Often commercialization of the media has accompanied democratization, and this has led to a dramatic reorientation of journalism, in many cases, away from serving government officials and toward the mass audience, sometimes resulting in rapid shifts from 'protocol news' to sensational crime reporting. In many cases, however, early visions of the emergence of independent journalism oriented toward public service have been undercut, sometimes by violence against journalists, often connected with the rise of drug cartels (Mexico, Honduras); sometimes by political polarization (Venezuela, Ecuador); and sometimes by reconsolidation of control by a new power center (Russia).

Internationalization

News media have developed primarily within the context of national political systems. There has always been some degree of international influence and exchange, most notably, starting in the late nineteenth century, through the role of the global wire services, which were an important basis for Western dominance of the flow of world news. But most journalists worked within a primarily national context. Most still do, but the internationalization of journalism has clearly accelerated. The advent of CNN as a global news service was an important step in this direction. The most important contemporary example is Al Jazeera, which, along with some other forms of pan-Arab television, has created an increasingly significant transnational public for news within the Arab world. The Internet has also made news increasingly accessible across borders.

New Technologies

The Internet and other forms of digital technology are changing journalism in many ways. They have undercut the separation of technology-based forms of journalism, particularly television and print, as Web-based journalism combines both. They have changed the timescale of journalism from the periodic cycle of daily news to a more continuous flow. They have provided new means for dissemination of news, and increased the audience for many news organizations, though often it has been difficult for news organizations to 'monetize' their online audiences, and the Internet has contributed to the collapse of the business model of newspapers. And they have displaced professional journalists in important ways from the central role they once played as 'gatekeepers' of news, as other actors, including politicians, political institutions, interest groups, and individual citizens, can disseminate news and information directly to the public. Much of the information circulated on the Internet is still produced by journalists for major news organizations, and in that sense the continuing importance of journalists in the flow of information should not be underestimated; often bloggers and other citizens recirculate and comment on what appears in the 'mainstream news media' rather than gathering information as professional journalists do. But there are many examples where these nonprofessional actors have major impacts, where video shot by citizens with cell phones becomes central to reporting, for example, or where a public is built around some political issue first in the 'blogosphere' and later is taken up by professional journalists (Williams and Delli Carpini, 2011).

Journalism and Journalists

Abstract

Journalism was born in the seventeenth century as a supplementary, part-time occupation of printers, postmen, or tradesmen; with industrial and bourgeois revolutions, it became fully institutionalized in the mass media. In earlier periods, journalists largely belonged to self-sustained free professions of the middle class; with industrialization they joined the class of workers employed by the press publishers. In the age of media digitalization and convergence, an increasing number of journalists belong to the precariat class or – according to the 'ideology of nonprofessionalism,' which suggests that 'everyone can be a journalist' in the digital age – they are not (considered) part of the professional journalistic workforce at all. Journalists are commonly associated nationally into trade unions and professional associations. The largest international association of journalists is the International Federation of Journalists.

The journalist is the key employee of news organizations who, in the definition adopted by the International Labor Organization, "researches, investigates, interprets and communicates news and public affairs through newspapers, television, radio and other media"; main tasks of journalists include "collecting, reporting and commenting on news and current affairs for publication in newspapers and periodicals, or for broadcasting by radio, television or webcast media." Due to national peculiarities in labor statistics and recent developments in 'online journalism,' a global estimate of the number of journalists remains quite unreliable. International Federation of Journalists (IFJ) claims to represent around 600 000 members in more than 100 countries (2012). Most journalists are employed in the United States, Japan, Germany, and the United Kingdom.

Journalistic work is primarily based on the *symbolic manipulation* of the content (sense making) in contrast to those, like typographers, responsible for the *mechanical* production of the newspaper or other news medium. In large and complex electronic media systems, journalism is contextualized and codetermined by other media output and occupations. Several groups of employees, who are occupied with symbolic manipulation or involved in administrative and organizational tasks, are conventionally not considered journalists. The development of electronic and, in particular, digital production and distribution of media contents, and the growth of new formats and genres of journalism (e.g., tabloids in the newspaper industry; talk shows on TV; blogging, social media in the Internet; hybrid genres such as 'infotainment' and 'advertorials') brought about numerous occupational groups (technicians and other employees in broadcasting, documentary production, audiovisual workers, computer programmers, designers) whose work cannot be classified exclusively into either side, i.e., they participate in both symbolic and technical (re)production of contents. The boundaries between journalism and nonjournalism, and between full-time and part-time journalists become even more problematic in the cyberspace dominated by a constant flux of information produced, reproduced, and distributed by millions of Internet 'visitors.'

There is no uniform 'journalistic culture' or concerted form of professional operation of journalists that would lead to a single concept of journalistic work and norms. In contrast to the rather technical meaning of journalism in English and most other languages of Western Civilization referring to the workforce in institutionalized forms of (mass) communication, the Greek concept of journalism, *δημοσιογραφία* (*demosiografía*), means 'writing about/for the people' and is focused on the social substance of journalism by emphasizing people rather than a particular class, or nature. Since *demos* means more than population but *citizenship*, journalism implies political relevance, which indeed was its most significant common trait until very recently. A critical labor perspective in the 1960s led to the concept of *newsworkers*, suggesting a distinction between news and entertainment or fiction without solving the problem of a clear sociological referent of the concept. In the Muslim world, journalists are required, similar to those in the West, not to 'mix truth with falsehood' and to verify news, but reporting is not allowed to be conceived on suspicion, to ruin people's reputation, or to mock them, and most importantly, news must have a 'use value' in that it must provide benefit (*Nafa*') to the people. The latter idea was central to 'development journalism' emerging in the 1960s in developing countries, emphasizing that reporting should contribute to national development of the country concerned. Similarly, 'public' or 'civic journalism' movements in the West in the 1990s suggest that journalists should not merely report, but discover a community's 'relevance' by meeting the people and experiencing their lives.

People have always passed on information from one to the next, but journalism as a distinctive occupational task did not begin until the seventeenth century, when it became a supplementary, part-time occupation of otherwise professionally committed individuals in the social communication process – e.g., printers, postmen, or tradesmen. Modern journalism, as a result of industrial and bourgeois revolutions, became fully institutionalized with the mass media. During that period, the press was largely liberated from censorship and party subservience. R. Park noted that the rise of the reporter had been one of the most important events in the 'age of news.' While in earlier centuries, journalists largely belonged to self-sustained free professions of the middle class, with industrialization they joined the class of workers employed by the press publishers. The separation between the occupations of publisher and journalist was followed by the establishment

of national and international professional organizations and trade unions of journalists.

During the nineteenth century, newspapers were generally still closely linked to political parties and journalists subject to the political credo of newspapers. The idea of objectivity represented an alternative to partisan journalism and a way to legitimate the professional status of journalists. The quest for objectivity was related to the need to establish a sort of professional, scientifically validated method for journalists to ensure their professional autonomy based on a 'standard' university education, also typical of traditional professions. The idea of journalistic objectivity as a professional norm was not widely recognized until the end of the World War I. In the early 1900s, the demand for objective reporting was embedded in the broader cultural movement of 'scientific naturalism,' which stressed the importance of methods in giving evidence of facts.

The conflict between subjective storytelling (the blending of facts and opinions, real events and trivial fictional material, news and entertainment into a tightly packaged story) and 'objective news' (the classic function of journalism to sort out factual and reliable accounts of daily, particularly politically relevant events) was never solved. The growing number of journalistic *codes of ethics* since the beginning of the twentieth century to mark professional standards in journalism has never resulted in a single code that would universally define the standard of 'objectivity,' including the professional standards adopted by IFJ. There are two main reasons: (1) The two tendencies of storytelling and objective reporting are not mutually exclusive but intermingling extreme strategies in reporting events; and (2) The competition for consumers causes competition for the latest news and makes journalists vulnerable to politics; political authorities enter journalism either directly through interviews and press conferences, or indirectly through 'information subsidies' (making information available to journalists on a *quid-pro-quo* basis), which influence the journalistic agenda setting, if not attitudes and actions, and eventually make journalism subsidiary to *public relations*. For example, in Japan, news sections of newspapers are produced in close cooperation with powerful news sources in government, industry, and the civil service, organized through the 'press club' system.

Journalism lacks the objective criteria – stressing the importance of universal norms, service to clients or altruism, intellectual activity and scientifically based expertise, autonomy and responsibility, and ethics – that would place it in the same social position as 'true' professions such as medicine or law. In many countries journalists have no specific professional standards to meet, which became even truer with the most recent development of 'digital journalism' in the Internet. The rise of the Internet and other technologies has radically changed the production and diffusion of news; an array of new authors, web publishers, and journalists, professional and nonprofessional, were brought in to create and distribute news online.

Although national codes of ethics share some 'universal' norms such as prohibiting editorial advertising and misleading audiences, protecting individuals against invasion of privacy, defamation and damaging publicity in general, and social groups against hate speech, it is increasingly difficult to enforce them in the online environment. Specific forms of (self-)regulation such as courts of honor, press or media councils, or press or media ombudsmen exist in a great number of countries to supervise the implementation of ethical standards by professional journalists and the media. They may be composed of journalists alone (as in the case of courts of honor within journalist associations) or representatives of the general public and media organizations.

There are invariably controversies between scholars, media workers, and media industries about the structure of journalism studies and the type of education needed for journalists. Early courses in journalism were mostly practical or vocational and connected with on-the-job training. In the 1920s and later, journalism curricula expanded into social sciences and included courses such as communication theories, public opinion, history of journalism, and ethics. The number of educational institutions in journalism has been growing throughout the twentieth century, starting with the University of Missouri in 1908 in the United States (which at present has 350 schools of journalism; one-third of them accredited at the university level) and soon followed by other regions in the world, where educational programs and materials were largely based on those from the USA and Europe. One of the first journalism schools linked to universities was set up in 1918 at the National Peking University in China. In Latin America, the number of journalism faculties and schools increased from 13 in 1950 to almost 300 by the end of the century. There is no 'typical' journalism curriculum, but it usually combines journalistic and nonjournalistic courses, with the prevalence of the latter (e.g., in the USA in a ratio 25–75). Many schools offer specialization in print, radio and television journalism, public relations, and advertising; fewer have more specialized programs, e.g., in photojournalism, magazine journalism, or television documentary. Generally, two seemingly contradictory trends may be found in the development of journalism programs: more and more specialized and even fragmented curricula in different fields of journalism on the one hand, and a more 'generic' approach to journalism stressing the need for instruction in communication skills cutting across specific job demands and combined with nonjournalistic specialization, such as arts, agriculture, economics, law, or politics. Both trends are restricted to larger and developed countries where many universities and schools can compete to 'supply' journalists to widely differentiated media.

In the developed world, a large proportion (often exceeding 50%) of newcomers to the profession graduate in journalism at a university or its equivalent. An international comparative study indicates that on average, students choose journalism as senior teenagers, primarily because they believe that the work of journalists is interesting and useful for society, and that they personally are talented for this job. However, many of those who graduate in journalism never enter a journalistic career but rather other communication-related or even noncommunication occupations. Specific education is not a necessary condition to enter a journalistic occupation. The lack of entry conditions such as agreed upon professional qualifications and licensing may be related to the liberal idea that freedom of expression and press freedom should not be restricted in order not to violate fundamental citizens' freedoms. Almost all countries outside the United States have a body of press or media law but journalists have no special legal status other

than defined by the constitutional rights and freedoms of citizens and, in some countries, some minor state legislation, e.g., the protection of information sources. Nevertheless, media owners and editors may define specific qualities and conditions that candidates for journalism must fulfill, and journalists may use mechanisms such as codes of ethics and forms of self-regulation to protect not only group autonomy but also monopoly in the labor market.

The lack of formal education in terms of theoretically grounded knowledge within a particular field contributes to the controversy about professionalism in journalism. Acquisition of such knowledge is central to the selection processes (search for the 'right' person for a job), and instrumental (skills) and expressive socialization (norms, ethics), by which entry into a profession may be controlled. The latter dimension of socialization gives primacy to the intellectual component of professionalism and to the production of expert knowledge, resulting from research. In 1922, W. Lippmann complained that no research had been conducted in the field of journalism despite its immense impact on democratic life. Although German *Zeitungswissenschaft* studied systematically the press beginning in the nineteenth century (e.g., journalistic genres, economics of newspapers), M. Weber was the first to suggest in 1910 to pay attention to journalism as a profession. He explained that a sociology of newspapers ought to include the study of journalists, part-time journalists, and other newspaper employees; 'collectivism and individualism in the creation of the content of the newspaper'; 'the anonymity of newspaper' and its effects upon journalists; cultural specificities influencing journalism and the social functions of the press; and 'the fate and the situation of journalism as a profession' (particularly the questions of education and professional demands upon the journalist). Weber's ambitious research program was not systematically carried out until the 1950s when during the rise of 'mass communication as a scientific discipline' in the United States, journalists became the subject of empirical research. Similarly to university education, however, studies in media occupations and professionals were not always well received by working journalists.

Before the rise of online journalism, in most countries journalists were closer to lawyers and politicians than teachers or public servants in terms of prestige and salaries. They were part of local and national élites although they were on average much younger if compared to other professions. Particularly, journalists in developing countries began with rather high social status. Generally, however, the journalists' opportunity for internal promotion within profession was limited even then. Comparatively low pay, inadequate work conditions, routine work, and limited opportunities for vertical mobility are key factors of horizontal mobility of journalists. They often move to other media fields such as public relations or advertising, and less frequently they leave the field of mass media, e.g., by moving to politics.

Since the 1990s, the rise of the Internet and digitalization of the traditional mainstream media led to the decline of the traditional media (particularly newspapers), stimulated the development of new online genres, and changed the nature and social (professional) status of journalism. These processes also brought about practices once incompatible with professional journalism, such as free Internet publication of newspapers' content to attract more advertisers; the flood of free media financed by advertisements; free 'public relations articles' replacing news stories and thus undermining newspaper credibility; advertising on editorial pages – undermining newspaper credibility even further; and particularly, reduction of editorial staff and newsroom budgets. In addition, strong professional mobility between the worlds of journalism and politics, which was particularly characteristic of the former socialist countries, and a too close relationship of journalists with advertising, entertainment, and public relations may severely endanger the autonomy of journalists and mute their critical voices.

However, when journalists are critical to political and commercial events and actors, as in 'investigative journalism,' they are often exposed to intimidation and harassment by the elites, and even assassinations are used to silence unwanted journalistic voices not only in wartime, or against war correspondents. In 21 years since 1990, when the IFJ has been issuing annual reports on the killing of journalists and media staff, 2271 journalists and media staff were killed or murdered in the course of their work, and many other disappearances were listed as under investigation by IFJ and the International Press Institute. The killings are only the tip of an iceberg of physical assaults and jailings, which affect journalists every year. However, the most widespread and epidemic peril of independent journalism in many countries is an increased number of lawsuits against journalists based on the legal provisions that the media should not harm the rights to privacy and reputation of individuals (including public officials); libel actions may be a disguised way of preventing journalists from performing a 'watchdog function' in society. Civil libel compensations became a sword of Damocles particularly in Eastern Europe and Russia in the 1990s, but prosecutions of journalists and high compensations threaten the media with bankruptcy and generally dampen investigative journalism in many other countries with a longer democratic tradition.

In terms of social and demographic characteristics, journalists do not represent the population of citizens who rely on their reporting and interpretations, but are expected – like other professions – to carry out their work in the interests of the audiences rather than their own interests. Such expectations may be disputed by the facts that professional journalists disproportionately originate from the families in which professional and white-collar occupations prevail, live in elite neighborhoods, are disproportionately male (although this disparity is lessening during last decades), and their views of the world commonly depart from those of an 'average citizen,' usually leaning toward more liberal and democratic political views, in contrast to technical staff in media organizations who are usually more conservative. For example, in a 2000-*Los Angeles Times* survey, 82% of US journalists were found to back abortion compared to only 49% of the general population. This is not to argue that journalists are a politically coherent population. In some countries, such as Italy, journalists are clearly 'divided' among different political affiliations, a tendency advocated by some contemporary regulatory measures supporting (in the case of press also subsidizing, e.g., in Norway and Sweden) diversity and political plurality of the media.

The composition of the journalistic workforce is generally becoming more diversified in terms of gender, but men still

represent the majority of the journalistic workforce. The increase of the number of female journalists indicates that journalism is no more a male preserve, but it also reflects a tendency of the intimization that permeates journalism. Yet the proportion of female journalists is still lower than the proportion of female students of journalism; female journalists are concentrated in the junior posts and in the nonnews sector (e.g., magazines), but the number of women producers, executives, chief editors, publishers, and other decision-making positions remains very low (in some countries even below 10%) and they tend to be paid less than men despite the fact that they are, on average, better educated than their male counterparts. The differences may be partly a consequence of the fact that female journalists relatively recently entered the profession, but they also may have to do with discrimination against women in journalism.

The rise of digital journalism and global recession that started in 2007 radically transformed the publishing world, and the nature and structure of journalist jobs. More and more newspapers, magazines, radio, and TV stations cut down their workforce in order to lower expenses and become more competitive on the market, or they had to close down altogether for the loss of audiences or advertising revenues. As all media got digitalized to attract particularly young audiences, which largely are not reading conventional news any more, and the Internet became the mode of carriage for all traditional press and broadcast media, journalists are increasingly supposed to master digital communication tools from traditional e-mail services to robust interactive Web sites. They are expected to be able to do everything in the digital environment with converging platforms: interviewing and writing, audio and video recording, photographing, and producing graphics. By repurposing the existing content in different (offline and online) platforms, fewer journalists can produce more. In consequence, traditional news media are often believed to have decreased professional standards of journalism to the detriment of objective reporting on current events and in-depth analysis of controversial national and international affairs, in order to remain competitive on the global market. An increasing number of (particularly young) journalists are not part of the professional journalistic workforce or they belong to the precariat class with part-time jobs and no job security.

These changes also spurred an 'ideology of non-professionalism' suggesting that 'everyone can be a journalist' in the digital age. Individual citizens – 'citizen journalists' – may present news through their blogs or online media services without being 'professional' journalists. The traditional editor or journalist is no longer a gatekeeper who selects news. Citizens are journalists and editors by themselves and for themselves, up- and downloading what they want with their personal computer devices. Due to the low cost of modern communication technology, the difference between digitalized traditional mainstream media (such as online newspapers) and new digital nonmainstream media (such as individual blogs) in terms of audience size and production costs is becoming less indicative than it used to be in the traditional divide between the mainstream and alternative media.

The competitiveness of commercially driven 'citizen journalism' where citizens – in addition to advertisers – play an active role by collecting, reporting, analyzing, and distributing news is best exemplified by the South Korean 'citizen journalism organization,' *OhmyNews* (www.ohmynews.com) with the motto "Every Citizen is a Reporter." The online newspaper, which was founded in 2000, now employs 70 full-time staff members; it has 62 000 citizen contributors sending 150 stories each day for no or (exceptionally) very low fee, and more than 2 million daily users. In addition to the Korean language site, it also has an English (OhmyNews International) and Japanese site.

The same hybrid development in 'global participatory citizen journalism' was followed by many other commercial news providers, including *CNN iReport* (http://ireport.cnn.com/) launched in 2006. Stories provided by members of the CNN audience are published on *iReport* Web site without being edited unless they are made part of CNN's 'professional' news coverage on CNN television and CNN.com. iReport claims to 'receive a submission from every country on the planet with an average of 2.4 million unique users each month.' Whereas this hybrid model of journalism is no doubt profitable for the owners, it represents a brutal devaluation of the labor of newsworkers. Changing patterns of journalism and the murky future of journalism as a vocation and full-paid occupation threatens to bring journalism close (back) to what Weber (1919) suggested a century ago: "The journalist belongs to a sort of pariah caste, which is always estimated by 'society' in terms of its ethically lowest representative."

The least ambiguous mark of 'professionalism' in journalism is the establishment of professional organizations. Journalists are commonly associated nationally either into trade unions or professional associations; frequently, their organizations combine both these functions. Yet a long-term tension exists between professional associations, which stress the professional status of journalists (and usually also include employers and managers), and trade unions, concerned primarily with collective negotiations on behalf of working journalists (newsworkers) with employers. Journalists often tend to define themselves as experts claiming to be above politics, but in some countries, journalistic associations also pursue political goals. The criteria for membership of journalists' trade unions and professional associations are fluid, particularly in relation to part-time journalists and 'boundary occupations' such as public relations. Trade unions of journalists negotiate for salaries, working conditions, and fringe benefits, and in some cases they also protect journalists' independence, e.g., by financial support to journalists penalized for refusing to do work incompatible with the professional standards (National Union of Journalists in the UK) or, as in France, by effectuating the same benefits to journalists who would leave jobs because of the substantial political changes in the editorial policy as to those who lose their jobs involuntarily. In many situations unions also serve as 'tools of the employer' because an imbalance in power exists between unions and employers due to the lack of unity among unions and guilds, their weak economic position and goals narrowed to individuals' rewards.

The largest international associations of journalists and media staff are the International Federation of Journalists (IFJ) and the Union Network International (UNI) Global Union, replacing Media and Entertainment International (MEI). First established in 1926 and relaunched in 1946 and 1952, IFJ is

the largest international journalistic organization with 600 000 members and 140 member unions in 125 countries on all continents (May 2012). The aims of IFJ include the promotion of international actions to defend press freedom through autonomous national trade unions or (as in the USA) guilds of journalists and other 'authors,' representation of journalists in the international trade union movement, and assistance to journalists and their unions in fighting for their professional and industrial rights. Journalists from socialist and some other countries established in 1946, the International Organization of Journalists (IOJ) as the counterpart to the IFJ. The IOJ, which also claimed the IFJ of 1926 as its predecessor, was dissolved in 1991 after the collapse of socialism. Members of 'technical' occupations in the arts, audiovisual, cultural, entertainment, and mass media sector who formerly represented the bulk of the membership of the MEI, merged in 2000 with three other international union bodies into the UNI, which represents 15.5 million members in 900 unions from more than 140 countries (May 2012).

Abstract

The journal plays a central role in scholarly communication. Its core functions of registration, certification, dissemination, archiving, and rewarding have remained intact so far across the online transition and the exploration of new publishing models like open access. Peer review is critical to the journal, and remains widely supported despite some robust criticism. New technologies have the potential radically to reimagine the online journal, but conservative scholarly communication behaviors suggest that future innovation will be evolutionary rather than disruptive.

Journals and Scholarly Communication

The journal – born in, and emblematic of, the Enlightenment – remains central to most fields of scholarly endeavor and of growing importance even in those fields where the monograph has previously held sway. In many ways, its transition to the online world has been smoother than for other media, preserving its core functions, its visible appearance, and its business model. At the same time, its details have never been more contested.

To understand the journal, we should consider it as an integral part of the wider system of scholarly communication, and bear in mind that the exponential growth in journals and articles is not a creation of the publishing industry, but is a consequence of the growth of investment in research.

Scholarly communication takes place across a spectrum from informal to formal. At the most casual are communications between individual researchers: e-mails, telephone calls, and conversations at conferences. Blog posts, still rare in most fields, are rather more formal (they can have quasi-persistent uniform resource locators, and editors increasingly allow their citation). Preprints and working papers are situated significantly further along the spectrum, followed by conference presentations and papers, and at the most formal, the journal article and scholarly monograph.

Defining the Journal

History of the Journal

The first journals were established in the 1660s; the first were *Philosophical Transactions* and the *Journal des Scavans*, established, respectively, by Henry Oldenburg on behalf of the Royal Society and Denis de Sallo in Paris. They took advantage of then new technologies – the printing press and the postal service – to distribute the findings of learned society members, and (crucially) to establish priority over claims.

The Five Core Functions

Within the scholarly communication system, the journal's role is substantially wider and more important than just the dissemination (or 'publication') of results. Its functions are usually seen as follows:

- *Registration*: third-party recording of the author's precedence and ownership of an idea
- *Certification*: providing quality control and establishing the validity of a scholarly claim through peer review
- *Dissemination* or *Awareness*: communicating the findings to the intended audience
- *Archiving*: the preservation of the scholarly record over time
- *Reward*ing: participants (primarily authors) are rewarded for their performance based on various metrics derived from the scholarly communication system.

Journals play an important navigational role in filtering readers' finite attention on relevant articles. There are a large number of journals, and even within individual specialist disciplines there can be many more journals and articles published than an individual researcher could ever hope to read. Although the 'article economy' is increasingly important, the filtering of publications by journals focused on particular topics, serving a particular community, and stratified by quality or significance of findings remains important.

Publishing in journals is thus an integral part of being a researcher in most scholarly fields. It connects them to other researchers in their field and keeps them abreast of developments. It allows (at least in principle) work to be repeated and the results tested. It provides a permanent record, sometimes referred to as the 'minutes of science,' on which future work can reliably be built. Researchers benefit from the promotion and dissemination of their work and gain recognition, credit, and funding in the process.

In the print world, these canonical functions (registration, certification, etc.) were bound together in the physical medium of the journal. Many commentators have pointed out, however, that this need not be the case in the online world: the journal could be disaggregated, and in particular the dissemination function could be separated from that of certification. We will return to this idea under 'Peer Review.'

The Journals Publishing Cycle

The movement of information between the different participants in the journal publishing process is called 'the publishing

 http://dx.doi.org/10.1016/B978-0-08-097086-8.41037-8

cycle.' The author's article passes through peer review and (if accepted) on to the publisher, thence to subscribing institutional libraries – typically via a subscription agent – before ending up back in the hands of the reader. In the world of electronic publishing, of course, readers also obtain journal articles directly from the publisher. This is a 'cycle' because scholars then build on the ideas and information in published articles to formulate new research questions and hypotheses.

In this traditional model, there is a clear-cut distinction between the informal and the formal, the unpublished and the published.

An emerging (though minority) model adopts a more open perspective: early drafts (with closed dissemination) are followed by preprints (open dissemination), open prepublication peer review, formal publication (open distribution), and then discussion and reuse through which various kinds of post-publication review and evaluation take place.

Peer Review

Central to all this is the role of peer review, which both endorses the quality of the researcher's work – its validity, significance, and originality – and brings about improvements to the quality of published articles.

Types of Peer Review

The main difference between approaches to peer review has been in the extent to which the authors' and reviewers' names are known to each other or hidden ('blinded').

The most common has been single-blind review, in which the authors' names are known to the reviewers, but the reviewers' names are withheld from the authors.

Double-blind review is the next most common approach after single-blind; here neither the authors' nor the reviewers' identities are disclosed to the other.

Open peer review is a poorly defined term, with the 'openness' applying variously to the actors' identities, to the submitted manuscript and/or the reviewers' reports, and to the set of people able to comment on submitted manuscripts. In most variants, the authors' and reviewers' names will typically be known to each other, though journals then vary on whether the reviewers' names are subsequently made public. Some journals, however, use open review to describe the publication of the reviewer reports and editorial correspondence even if this remains anonymous.

Critiques

For all its totemic status, peer review is far from immune to criticism. The comprehensive set of charges leveled at it concerns its validity, effectiveness, efficiency, and fairness.

The charge that there is an absence of reliable empirical evidence that peer review leads to a higher quality of research (as opposed to research publications) seems damning. The absence of evidence is not the same thing as evidence of absence, though, and the critics accept that this is both a high hurdle and a question of considerable difficulty to test in the real world.

Various studies have shown peer review indeed lacks effectiveness in some areas. For instance, it has been shown to be unreliable (e.g., interreviewer reliability is generally low), and not very good at detecting errors. It also adds delay to the publication process, arguably slowing down the dissemination and hence progress of science (Ware, 2011).

Peer review can be seen as a 'burden' on researchers, in the sense that it represents real work to be done, but this is generally accepted to be an appropriate part of the professional duties of academics.

The evidence for a 'crisis' in peer review, with growth in submissions overwhelming the numbers of available researchers, is weak. Research outputs are correlated directly with the number of active researchers, so more research outputs means more potential reviewers. There may, however, be transitional regional imbalances.

Peer review is also criticized for its potential unfairness. Single-blinded review clearly allows scope for reviewer bias or misconduct. Journals are exploring the increased use of both double-blinded review and of more open review to mitigate these flaws.

New Developments in Peer Review

The foundational role of the peer-reviewed journal in the scholarly record, combined with its importance in evaluating research, is reflected in a conservative approach to peer review. Despite this, there has been a significant degree of innovation during this century, aided by the potential of the Web to support new approaches. These can be divided into attempts to improve the prepublication review process, and those that seek to add a layer of review after publication.

Starting with prepublication changes, the change with the biggest impact to date is probably the 'soundness not significance' approach. Reviewers are asked to assess the technical soundness of submitted papers, but not to judge them by the allegedly more subjective criteria of impact or significance. The approach is frequently associated with open access (OA) journals.

'Cascade' review allows the reviewers' comments (with the author's consent) to follow a manuscript when it is rejected by one journal and submitted to another. It plays some part within publishers but attempts to implement it across publishers (such as the Neuroscience Peer Review Consortium) have had limited impact to date, though new initiatives continue to emerge.

A more radical change would be to separate peer review from individual journals entirely, with the review being carried out separately and reviewer reports being attached to manuscripts for the benefit of any journals to which the author chose to allow access. At least two organizations had begun to offer such services as of mid-2013.

The other new approach to peer review is to conduct assessment of research articles after publication rather than before.

In its most radical form, a system of postpublication review would see papers published without prior review (beyond minimal screening), with various kinds of appraisal, rating, and review, both formal and informal, taking place subsequently, and combined with metrics reflecting usage and impact.

Proponents argue that filtering prior to publication is ineffective, and is costly and time consuming.

A more pragmatic approach to postpublication review sees it complementing conventional review, rather than replacing it.

Publishing Ethics

While misconduct in research and scholarly communication remains unusual, it does happen and may be more common that most would like to believe. We can distinguish between misconduct in research and in publishing, though there are some overlaps. Research misconduct at its most extreme includes fabrication and falsification of data, as well as omitting or discarding data that does not support the authors' research, overoking use of flawed data, or not maintaining adequate records.

Publishing misconduct includes plagiarism, not citing others' work, not presenting work that contradicts their own, publishing the same data in multiple articles or multiple submissions, giving inappropriate author credits ('guest authorship'), not crediting an author ('ghost authorship'), withholding details of methodology, and undeclared conflicts of interest.

Growth in Article Retractions

The sharp rise in article retractions over the past decade is well documented. Data from the PubMed biomedical literature database show that retractions have grown both in absolute terms and as a proportion of articles published.

It cannot be determined from these data whether incidence of misconduct is increasing, whether the misconduct is now more likely to be detected, whether ethical standards have risen, or some combination of the three. The time between publication and retraction has fallen, which is consistent with improved detection, but does not rule out increased misconduct.

Committee on Publication Ethics

A number of organizations provide support and resources to journals and publishers in dealing with ethical issues, notably the Committee on Publication Ethics. The World Association of Medical Editors and International Committee of Medical Journal Editors also provide codes of conduct and other guidance.

The CrossCheck service brings a more technological approach to bear. It allows journals to screen submissions for potential plagiarism by using software to compare their content to a database of scholarly articles.

Using the Journal

Authors and Readers

It used to be said that the average scholarly article was only read by a very small number of people. This appears to have been a misunderstanding (King et al., 2006), but whatever the truth in the past, the usage data of electronic publishing have given the lie to this perception.

Some fields of study are of course small and specialized, but the overall audience for scholarly work can be large. There are estimated to be 6.5–8.5 million researchers worldwide (Elsevier, 2011; Royal Society, 2011). Their numbers are determined primarily by levels of investment in research and development, and are growing by some 4–5% per year; much of this growth arises in the emerging economies.

There is a distinction to be made between the core active researcher segment and the wider journal-reading community, which is likely to be much larger. We can think of a central core, where most readers are also active researchers, surrounded by an intermediate layer where users are regular readers but only occasional authors, in turn wrapped in an outer layer of occasional readers.

This readership profile will vary by discipline: in fields like pure mathematics or theoretical physics there may be little readership outside the core of active researchers, but in a field such as nursing or medicine, practitioner readers will be many times more numerous than authors.

Many of these additional readers may also be more peripheral and infrequent readers, including postgraduate and undergraduate students. There appears to be no robust evidence sizing this wider journal reader community but publishing industry estimates suggest a total global journal readership of around 10–15 million.

Scientific journal articles are written primarily by academics. For instance, Tenopir and King report that although only 10–20% of the scientists in the United States are employed in universities, they account for about 75% of articles published (King and Tenopir, 2004).

Reading Patterns

We know that journals are widely used within academia. Industry estimates put global annual downloads of scholarly articles at well over 1 billion (Ware and Mabe, 2012), and one study found that each UK registered academic library user downloaded a total of 47 articles per year (RIN, 2011b). The distribution of downloads roughly follows a power law, with a few highly accessed articles and a 'long tail' of infrequently accessed work.

Of course article downloads measure something different from actual reading. There is a long history of reading studies, however, and from these we know, for example, that the average number of articles read annually by academics increased from around 150 in the 1970s to over 270 in the late 2000s, while the average time spent reading each has declined (Tenopir et al., 2011). These pressures have led to what has been dubbed 'strategic reading' (Renear and Palmer, 2009), and to speculation that new software tools may in the future undertake at least part of this work on behalf of (human) readers.

Citations and the Impact Factor

The most tangible evidence for most authors of article readership and impact is a citation elsewhere in the peer-reviewed literature. Citations are central to scholarly discourse, helping the author build their arguments by reference to earlier work, and helping readers by pointing them to related work.

Citations have grown faster than the number of articles. The factors explaining this include the cumulative growth in the literature, more permissive journal policies allowing longer reference lists, and growth in coauthorship. There are big differences in average citation rates between disciplines, with most of the variation explained by differences in coauthorship rates.

Of course, citations play a central role in bibliometrics, notably in the Journal Impact Factor (JIF). The JIF, a proprietary figure produced by Thomson Reuters, measures the average number of times an article in a journal has been cited in a particular period. It was originally introduced to aid librarians in the selection of journals but has subsequently acquired a greater significance as a measure of the 'quality' of a journal. This focus on a single metric has inevitably led to 'gaming' strategies by editors and publishers.

The use of the JIF as a proxy for the quality of research outputs of individuals or departments is a particularly egregious misuse of statistics, since the distribution of citations is highly skewed, and JIFs depend on the research field and on technical factors unrelated to journal quality (Seglen, 1997).

Criticism of the overuse and misuse of the impact factor has led to a growth in the number of available metrics (for example, the *h*-index) and in the field of 'altmetrics.' The latter seeks to obtain a broader measure of article impact by combining multiple metrics and usage indicators.

Authors' Behavior, Perceptions, and Attitudes

While academics may be radical in thought, they are conservative in deed, at least when it comes to scholarly communication. Harley et al. (2010) found researchers remained focused on conventional formal publication, and cautious about new models of Web-based scholarly communication, a picture confirmed in other studies (e.g., RIN, 2010).

Despite a widespread transition to use of electronic journals over the past two decades, the core motivations of authors appear remarkably constant, in terms of a need for attribution and recognition, quality control (including peer review), and visibility. Securing funding and furthering their careers remain two key motivators for authors, albeit generally given as secondary to disseminating their findings. The factors used by authors to select journals for publication are also stable: perceived quality, relevance, and speed of publication remaining the most important, and support for peer review remains widespread.

We should also be cautious of the idea of the 'digital native,' a younger generation of scholars that grew up with Facebook and is alleged to lead the way in adoption of new digital media. Younger scholars showed similar patterns of behavior in these studies in their professional activities as their elders, whatever their nonwork behaviors, and in fact, well-established researchers appeared the most likely to lead adoption of new tools and media.

Disciplinary Differences

Journals vary by discipline. One obvious difference is size, with science and technology journals in the Thomson Reuters index more than three times the size of those in the humanities and social sciences. These differences reflect those in the underlying disciplines: researchers in science, technology, engineering, and mathematics (STEM) disciplines produce the most articles, followed by those in social sciences, and then in the humanities. Joint authorship also varies, with the highest levels again in STEM disciplines, especially biomedicine. The relative importance given to journal articles compared to other types of research output such as monographs is also highest in STEM fields, while a few fields favor (peer-reviewed) conference proceedings. There are also clear differences in attitudes to peer review, in reading and usage patterns, in citation behaviors, in the half-lives of cited and downloaded materials, in the importance of the certification function (as reflected in the willingness to use and formally cite un-peer-reviewed materials), and more recently in attitudes toward OA.

Long-Term Preservation

The continued use of today's journal content into the future depends on its long-term preservation. History has shown that acid-free paper, stored under the right conditions, can be preserved for centuries or longer. We lack the same experience with electronic media, but confidence in their longevity is important for the acceptance of electronic-only journals. New infrastructure is currently under development for the preservation of electronic media, including distributed storage arrangements that mimic the multiple print copies held by libraries, and digital archives maintained by national libraries. Challenges remain, however, in developing some aspects of the necessary technologies, and in the funding requirements.

The Journal in the Global Marketplace

Journal and Articles Numbers and Trends

There are a lot of journals: Ulrich's Directory records well over 28 000 peer-reviewed academic journals, collectively publishing some 1.8–1.9 million articles each year. The archive is correspondingly large and increasingly available online: at the end of 2012, the CrossRef database contained over 46 million digital object identifiers (DOIs) referencing journal articles.

An important subset is the 10 800 journals included in Thomson Reuter's Journal Citation Reports, of which 8400 are in the Science Edition and 3000 in the Social Sciences Edition: these collectively publish about 1 million articles annually. These journals are on average substantially larger than those not included, but their importance primarily arises because they are the most cited. The other major database, Scopus, is intentionally broader in scope, and covers about 20 000 peer-reviewed journals.

The number of peer-reviewed journals published annually has been growing at a steady rate of about 3.5% per year for over three centuries, with some acceleration in the postwar period 1944–78. The number of articles has also been growing by about 3% per year over similar timescales. This growth in the literature is directly correlated with (and likely driven by) the number of researchers in the world, which in turn is driven by the levels of research and development (R&D) funding.

Global Trends in Scientific Output

Global spending on R&D has consistently outpaced global gross domestic product. This trend seems likely to continue as governments seek competitive advantage from their skills and knowledge bases, and see R&D as critical to innovation and economic growth.

Consequently, we should not be surprised to see the fastest growth in journal article output in the large emerging economies that have prioritized R&D investment. China has overtaken the United Kingdom to publish the second largest annual number of research papers, with its share now at over 10%, and is set to overtake the United States well before 2020.

Journal Market Size and Economics

Journals are not just a core part of scholarly communication; they also represent a substantial market valued at about $9–9.5 billion, with books worth a further $3.8 billion. Journal revenues derive mainly from library subscriptions and license fees (68–75% of the total revenue), followed by corporate subscriptions (15–17%), advertising (4%), membership fees and personal subscriptions (3%), and various author-side payments (3%) (Ware and Mabe, 2012).

On the cost side, one of the more reliable estimates of global costs was made by Cambridge Economic Policy Associates (RIN, 2008; updated for RIN, 2011c), giving the average 2010 journal article cost of production (print + electronic) at £3095. This was made up as follows: first copy costs (the costs incurred regardless of the number of copies distributed, e.g., peer-review management, copy-editing, typesetting, and origination): £1261; variable costs (printing, paper, distribution): £581; indirect costs (staff and overheads): £666; and surplus: £586.

Researchers' Access to Journals

The extent to which researchers have adequate access to journal content has been a contested area. There is no doubt that the 'Big Deal' and similar bundling models (in which consortia of libraries purchase online access to additional, previously unsubscribed journals from a publisher at heavily discounted rates) have led to a large expansion of access. This of course came at a cost, including squeezing smaller publishers' share of library budgets, but has documented benefits in terms of sharply increased availability, usage, and decreased cost per download (RIN, 2011b). Many groups that could benefit from access have nevertheless found themselves excluded from such arrangements, leaving access gaps at corporations, small and medium enterprises, independent professionals such as engineers, clinicians not attached to research/teaching hospitals, and others.

Paradoxically, measures of researcher satisfaction and dissatisfaction are both high. For instance, in a 2011 survey, 93% of researchers described their access as easy or very easy, and yet 39% of the same respondents said their top priority was to improve access (RIN, 2011a). The likely reasons for this are that 'easy access' is no longer good enough; researchers can be frustrated by knowing that essentially all articles are available online somewhere; and the improvements in search engines and other discovery tools means that relevant research is ever more visible.

One special case is access in developing countries. Research-4Life, a collaboration between publishers and various United Nations agencies, provides access either free of charge (for the poorest countries) or at very low rates.

Open Access

OA refers to the making available of content (especially, though not exclusively, journal research articles) in online digital copies, free of charge, and free of most copyright and licensing restrictions, and free of technical or other barriers to access (such as digital rights management or requirements to register to access).

The combination of electronic delivery, bundling models, and philanthropic schemes, has significantly improved access to scholarly content. This has by no means reduced pressures for OA, however, and OA journals are by far the fastest growing section of the market.

Gold and Green Open Access

There are two broad approaches for journal articles: 'Gold' OA is a publishing model in which journals make the final published versions of articles freely available immediately on publication. By contrast, 'Green' OA is a sharing or distribution model in which a version of the article is archived in, and made available from, an open repository, either immediately on publication or following an embargo period.

The most common business model (by numbers of articles) for Gold OA publishing is the article processing charge (APC). Green OA does not have a self-sustaining business model itself, but assumes journals' business models will remain unaffected by the free parallel distribution (or will flip to OA).

Other Open Access Variants

In addition to these primary forms, there are two notable variations. First, some journals make their full content freely available on the publisher's platform after an embargo period. Second, most subscription-based journals now offer authors optional OA at the article level (on payment of an APC).

System-Wide Perspectives

If the goal of wider access is widely supported, the details of implementation and the relative benefits of particular approaches and public policies have been heavily contested.

The main drivers of OA have been the interventions and policies of research funders and policy makers, together with the growth and maturing of the OA publishing sector itself.

Research funder initiatives have probably been the most important, including in the UK the Finch Group report and subsequent changes to public funding policies, and the policies and initiatives of the Wellcome Trust (which collectively have tended to give greater weight to the Gold model), and in the United States the 'public access' policies of the National Institutes of Health and (more lately) the White House Office of

Science & Technology Policy (which are more inclined toward the Green route).

Several economic studies have considered the direct and wider social benefits of OA. Whether moving to a Gold OA model in place of (or more likely, in parallel with) subscriptions would result in direct financial savings for academia will depend on the average APC. The wider economic benefits to society of OA to research outputs depend on long-term economic growth models; the approach may be valid but the outputs are sensitive to assumptions that are not easily tested (Houghton et al., 2009; RIN, 2011c; Finch Working Group, 2012).

Open Access Impacts on Use and Citation

Another contested area has been whether making research articles OA leads to increased citations. All work has confirmed a marked increase in downloads of OA materials, but studies differ on whether or not this is accompanied by increased citations (e.g., see Davis and Walters, 2011). Although the common-sense hypothesis suggests more views would lead to more citations, the best available evidence at this point suggests that OA articles do not receive more lifetime citations, but they do get them sooner.

Copyright Issues

A growing focus is on the rights to reuse content, not just to access it. This has led to a debate over the most appropriate copyright licensing regime for OA articles: the most liberal, the Creative Commons Attribution license (CC-BY) is widely endorsed by OA advocates, especially in the sciences, but many publishers and indeed authors and editors prefer more restrictive Creative Commons licenses.

New Developments in Scholarly Communication

Journal Publishing Platforms

There is no doubt that technology has had an impact on the journal and has the potential radically to reimagine it in the future (for instance, by separating its core functions), but to date the electronic journal remains remarkably familiar to users of print.

Apart from the increased efficiency of dissemination and of searching (and the large behind-the-scenes efficiencies in production processes), one could argue that one of the most important early advantages of e-journal platforms was the hyperlinked citation and 'cited-by' links, made possible by the development of the DOI and the infrastructure that sits behind it. Looking forward, we see journal platforms becoming more interoperable in ways that extend this simple idea, for instance, using semantic technologies and open Application Programming Interfaces (APIs).

New Forms of Electronic Articles

There is interest in exploring new forms of journal article. These range from attempts to improve the on-screen usability and functionality to more radical changes such as the recent introduction of data papers, and more radically the proposed nanopublications.

Data-Intensive Science

One catalyst for change will surely be the growth of data-intensive science. The explosion of data presents challenges, but also creates opportunities to increase the efficiency of research and its reproducibility through 'intelligent' data sharing (Royal Society, 2012). Journals are thus now developing policies with respect to data sharing. A new article type, the 'data paper,' is also emerging with the launch of data journals.

Semantic Web and Linked Data

Closely associated with data publication is the notion of the semantic Web. Present journals (at least in science, technology, and medicine) make considerable use of semantic technologies to enrich content, but the formal concept of the semantic Web remains complex, expensive, and elusive.

Semantic enrichment is the tagging of content to add value by identifying and linking terms and concepts of interest to a particular domain. The benefits include improved search and discovery, including matching content to user interests and behaviors; enabling new products and services such as semantically grouped collections, and facilitating text and data mining; and productivity gains in journal production and peer review.

Text and Data Mining

Text and data mining, which draw on natural language processing and information extraction to identify patterns and find new knowledge from collections of textual content, offer the potential to transform the way researchers make use of the literature (e.g., Nature, 2012). This potential has yet to be realized, however, and there are some substantial challenges still to be addressed, including access, licensing issues, data normalization, and others.

Social Media

One of the more obvious changes in the way the general public uses the Web has been the dramatic growth of social media. This has not been paralleled in scholarly communication, however, where uptake remains low and researchers stubbornly conservative in their preference for conventional channels. For example, a recent study estimated that only 1 scholar in 40 used Twitter (Priem et al., 2012) and other studies (noted above) put all forms of social media use at about 15% or lower. Use in some areas (including Twitter) is growing fast, however, and it seems inevitable that integration with the journal will gradually become more important. One emerging idea is that of open annotation.

Mobile Access and Apps

Similarly, despite the widespread adoption of smartphone, tablets, and other mobile devices, accesses by mobile devices

currently represent well under 10% of traffic at most electronic journal platforms. On current trends, increasing mobile access seems unlikely to change the nature of the journal much (in contrast to some of the other trends discussed in this section), but an important impact may be to accelerate a shift of personal reading from print to screen.

Identity and Trust

Two related concepts central to the value of the journal are those of identity and trust. In peer review, reputation is critical to the editor selecting the reviewers and evaluating their reports, and the same is as true for social media recommendations or open annotation.

An important problem has therefore been the disambiguation of researchers with similar or identical names, or with inconsistent transliteration of names from non-Roman alphabets, and the tracking of researchers across name changes. While there are proprietary approaches, a better system is now emerging in the form of Open Researcher and Contributor ID. This initiative provides a central registry (which permits researchers to create and manage their own records), and a Web platform to support system-to-system communication and authentication.

In Conclusion

The journal has thus proved a remarkably resilient format, little changed in its core functions since its introduction in the seventeenth century. Despite the professionalization of peer review in response to the rapid expansion of science following World War II, the commercialization of the sector in the decades that followed, and more recently the transition to the Web, the core functions of the journal – registration, certification, dissemination, archiving, and rewarding – remain intact, for now at least. Its central importance to scholarly communication has probably never been higher, and its role in research assessment and reward is still growing.

Abstract

From a religion that focused on sacrifices in the Temple of Jerusalem, Judaism emerged as a religion that required the implementation of religious laws by all Jews in their daily life. New patterns of Jewish identity in the nineteenth century involved a decline in religious observance and modifications in the synagogue services that represented accommodations to non-Jewish society. The patterns of religious observance today in the two largest Jewish communities, those of the United States and Israel, are broadly similar, but they differ in their religious affiliations and identities. Ultra-Orthodox Jews, whose numbers have increased considerably in recent decades, present a strong contrast with the secularized pattern of the majority.

From Israelite Religion to Rabbinical Judaism

Max Weber's *Ancient Judaism* (1917–19/1952) was the first comprehensive sociological analysis of religious changes in Ancient Israel. Weber recognized both division and continuity between the 'Israelite religion' of the period prior to the destruction of the First Temple in 586 BCE and the 'Judaism' that emerged from the period of the Babylonian Exile, the return of some of the exiles after 538 BCE, and the period of the Second Temple (516 BCE–CE 70). A genuine monotheism emerged only in the later period, but Weber traced its origins to a period when the Israelites constituted a confederacy of seminomadic stock breeders and warriors. The tribes and kin groups that made up the confederacy had, at first, their own separate gods, but as the confederacy became more powerful it became increasingly focused on one god. Weber emphasized the importance of the Covenant in this process as it both signified and promoted the uniqueness of the relation of Israel to its God. It was constituted of mutual promises: the people of Israel promised to obey God's law, and in return, Yahweh, who had already liberated them from slavery in Egypt, would grant them domination over the Promised Land and protect them from their enemies.

The gradual crystallization of the monotheistic idea continued during the period of centralized monarchy from the eleventh century and was advanced considerably by the new type of prophecy that emerged by the end of the sixth century BCE. Weber argued that the appeal of the prophets can be understood, in part, against the background of the development of the monarchy into despotic states, the demilitarization of the peasants, and mounting external threats to the Israelite kingdoms. The tradition preserved those prophecies that appeared to have come true, and it was during the Babylonian captivity, when the predictions of doom were seen to have come to pass, that the prestige of prophetic religion reached its height. A broad urban stratum whose lifestyle was not conducive to magic was responsive to ethical prophecy and became the carrier of religious, ethical action. Weber argued that changes in Ancient Judaism represented a significant development in ethical rationalization, but the influence of postexilic Judaism on Western society was limited because it remained a religiosity of law, centered on concrete, discrete norms rather than on abstract principles.

Weber's work influenced biblical scholars, but although a number of sociologists have attempted to systematize Weber's somewhat fragmented analysis, particularly with respect to the development of monotheism and rationalization, very few sociologists have attempted to expand upon Weber's analysis on the basis of subsequent findings of biblical scholars and archaeologists. Controversy remains among biblical scholars with respect to the development of monotheism. Some argue that there was little continuity between the preexilic and postexilic periods, claiming that monotheism emerged totally in the exilic (Babylonian) and postexilic eras, and they minimize or discount any significant preexilic contributions to its emergence. In these accounts, there was little to distinguish preexilic Israelite religion from so-called Canaanite polytheistic religions, and it was the religious elites of Yahwism in exile and in the postexilic period who fictionalized what became the biblical narratives for the preexilic era. Other scholars attribute greater importance to preexilic developments, such as the early shift, possibly from the late tenth century, to Yahwistic 'monolatry' (exclusive worship of a god enforced by prohibitions of allegiance to other gods without denying their existence), but they are also inclined to recognize the Babylonian exile as having an overwhelming impact that ensured the permanency of mono-Yahwism.

The assumption that early Israelite society was a seminomadic, tightly knit tribal league has been challenged by scholars who have proposed that it was primarily an agrarian society, composed mostly of peasants indigenous to Canaan who worshiped a number of deities in addition to Yahweh. The centralization of sacrificial worship in Jerusalem was a slow process before it gained ritual hegemony in the seventh century. The Covenant is now seen by many as established no earlier than the first half of the seventh century BCE, and one view is that it was originally conceived as between Yahweh and the king and later reformulated as between Yahweh and the people. In place of the idea that the roots of monotheism emerged in nomadic or seminomadic societies, scholars have emphasized the royal shrines at Jerusalem and the urban centers of Mesopotamia during the Babylonian exile as the major sites of the emergence of monotheism. There is little doubt that in all of these periods, different strata and groups of the peoples of Israel and Judea practiced a variety of religions (family, local, royal, or elite),

and that a uniform orthodoxy was not achieved (Gnuse, 1997; Gottwald, 2002).

In the most general terms, the transformation of Israelite religion into Judaism can be described as a change from a religion that had come to be focused on sacrifices and other ceremonies performed by the priests in the Temple in Jerusalem to a religion that emphasized the reading and teaching of the Torah, forms of prayer worship in the synagogue, and the implementation of the religious laws by all Jews. Elements that had been part of Temple worship, particularly with respect to food, were accommodated into domestic life, both on a daily basis and on festivals such as Passover. Some of the seeds of this transformation can be traced to the period of the Second Temple, particularly among the Pharisees, who represented one of a variety of 'Judaisms' alongside the Sadducees, Essenes, Christians, Samaritans, and other groups in the first century CE.

The changes in the religion and the identity of the people associated with the religion have prompted a debate among scholars of antiquity over the issue of when it becomes appropriate to use the terms 'Jew' (*Yehudi* in Hebrew) and 'Judaism' (*Yahadut* in Hebrew). At first, *Yehudi* referred specifically to the tribe of Judah (*Yehuda*), as distinguished from the other tribes of Israel, but the name came to designate anyone resident in or originating from the kingdom of Judah. S.J.D. Cohen (1999) argues that a semantic shift from 'Judean' to 'Jew' is justified from the latter part of the second century BCE, when the Greek term for *Yehudim*, *Ioudaioi* (singular, *Ioudaios*), came to be applied to people who were not necessarily geographic or ethnic Judeans but had come to believe in the God of the Judeans. A non-Judean could become a *Ioudaios* by joining the Judeans in worshiping and venerating the God whose temple was in Jerusalem. Critics of Cohen have argued that the semantic change is justified only at a later date. As a translation of the Greek *Ioudaismos*, 'Judaism' in antiquity has been understood to denote the religion and/or culture of Judeans or Jews, but there are very few uses of the term in Second Temple sources. 'Judaism' came to be commonly used in gentile Christian literature, but among Jews its use remained rare until modern times.

The destruction of the Temple in CE 70 and the crushing of the revolt in CE 132–135 proved to be decisive events in the transformation of the religion; the institutional base of the priesthood was gone, and Torah scholars emerged as the dominant religious elite. It was the sages of the religious academies of Palestine and Babylonia who produced, over the first six centuries of the Common Era, a huge corpus of religious literature that came to be known as the Talmud. Oral traditions were eventually edited around the year CE 200 into a large corpus known as the Mishna, and the subsequent voluminous commentaries on this literature came to be known as the Gemara. The Palestinian Gemara was completed in about CE 450, but it was the Babylonian Talmud (the Mishna plus the Babylonian Gemara), completed in about CE 600, that came to be accepted by most Jewish communities as authoritative (Cohen, 1987).

The term 'rabbi,' meaning 'my master,' came to be used to designate those scholars who created Talmudic Judaism, which became the dominant form of Judaism from around the turn of the first millennium until the nineteenth century. It took some time for the rabbis to be accepted as religious leaders, and during most of the period of the production of the Talmud, from the second to the seventh centuries CE, the rabbis had little impact on the vast majority of Jews. The rabbis appear to have recruited disciples who were literate, relatively prosperous Jewish males, but little is known of the social processes by which rabbinical Judaism came to be accepted among the communities of the expanding diaspora (Lapin, 2010). One social process that took place among the Jews during those centuries when Rabbinic Judaism was taking hold was their occupational transition from agriculture to urban occupations. It has been proposed that the transformation of Judaism into a religion centered on reading and learning provided the Jews with a competitive advantage in the new urban centers of the Muslim empire, especially during the Abbasid rule from the mid-eighth to the early ninth centuries, and later in the towns of Europe. The shrinkage of the Jewish population, far greater than that of the general population, from the first century until the early eighth century is explained by voluntary conversion, mainly to Christianity, of Jewish illiterate farmers who did not adopt Rabbinic Judaism (Botticini and Eckstein, 2005).

Judaism and Jewish Identity

An explicit distinction between the religious and ethnic elements in Jewish identity was made only in the modern era, but it is possible to trace how these elements came together and received canonical authority in Rabbinic Judaism. The rabbinic texts defined a Jew as a person who belongs to a particular descent group, 'the children of Israel/Jacob,' and the common ancestors were linked to a religious event. The 'people of Israel' had entered into a unique relationship with Yahweh through the covenants with Abraham, Isaac, and Jacob, and that relationship was more sharply defined through the Covenant at Sinai, an event that, according to the Rabbinic tradition, defines Israel (Porton, 1999). The rabbis of the second century CE standardized the conversion process by requiring that all converts accept the commandments of the Torah, that male converts be circumcised, and that all converts should undergo ritual immersion. This standardization provided a group identity with permeable boundaries. It was also in the second century CE that rabbinic law established the matrilineal principle: only the offspring of a Jewish mother were recognized as Jews. This ruling, which was surprising in the context of the patriarchialism of Israelite and Judean laws and culture, together with the prohibition on intermarriage, expressed the rabbinic concern for genealogical purity (Cohen, 1999).

The fusion of religion and ethnicity formulated by the rabbis came apart in the modern era when rabbinic hegemony came to an end and Jews were freed from the segregation that had been imposed upon them by non-Jews. Toward the end of the eighteenth century and in the nineteenth century, new patterns of Jewish identity developed in Europe and North America in response to secularization and the construction of new collective identities of modernizing nations. The construction of boundaries of citizenship and identity involved formulating terms for the Jews' inclusion or exclusion. Where secularization was accompanied by willingness to

include the Jews – often made conditional upon the Jews' adoption of the dominant culture and national identity – many reinterpreted their Jewish identity as a purely religious one and eschewed any Jewish national, or what came later to be known as Zionist, identity. Proclaiming that they differed from their non-Jewish compatriots only in terms of religious persuasion, the English people, French people, Germans, and Americans of the Jewish or Mosaic faith developed forms of Judaism (Reform, 'modern' or 'decorous' Orthodox, and later, in the United States, Conservative Judaism) that they believed would allow them both to participate in the wider society and to retain a religious identity as Jews. The religious observance of a large proportion of Western and Central European and American Jews in the nineteenth century came to be limited to the rites of passage, infrequent visits to the synagogue, and a few yearly observances in the family setting.

The forms and degrees of changes made within synagogue services varied among the secularized Western communities in the nineteenth century; Reform Judaism became important in German and American communities, whereas modified forms of Orthodoxy were the most popular in the communities of England, France, and Italy. These differences were related to the influences of the different forms of Christianity in the environment of acculturated Western Jews (Catholicism in France and Italy, Anglicanism in England, and liberal Protestantism in parts of Germany and the United States), and the extent to which economically mobile Jews were socially accepted by non-Jews in the middle and upper classes. One aspect of religious accommodation was common to all the secularized communities: the concern with decorum. Acculturated Jews disliked the outward emotionalism and demonstrativeness of the traditional service – the loud chanting of prayers, the body movements, the coming and going during the service, and the inappropriate business of selling religious honors, with congregants making material offerings when called upon to recite benedictions before and after readings of the Torah. The decorous Orthodoxy in, for example, the English communities provided rigidly patterned services with a passive audience of worshipers listening to the cantor, a choir, and regular sermons in the vernacular by the rabbi or 'minister.' The Reform movement in Central Europe and North America made far more extensive changes in the synagogue or 'temple' services; in addition to mixed choirs accompanied by an organ, mixed seating, and sermons in the vernacular, the liturgy was considerably abbreviated and many prayers were read in the vernacular. In the United States, a Conservative movement seeking a middle path between Orthodoxy and Reform emerged at the end of the nineteenth century. The Conservative movement attracted the children of immigrants from Eastern Europe and grew rapidly after World War II; its services had more Hebrew and were more traditional than Reform ones, but, like Reform and in contrast to Orthodoxy, mixed seating was allowed.

In Eastern Europe, where the construction of national and ethnic identities involved marking the Jews as unassimilable outsiders, the inroads of secularism and the breakup of traditional communities toward the end of the nineteenth century led many Jews to adopt a nonreligious national, ethnic, or cultural Jewish identity. This type was, in some respects, the converse of the type that had become common in Central and Western Europe and the United States. A greater proportion of secularized Eastern European Jews believed that their problems required radical solutions (a socialist revolution or an autonomous Jewish state), and religion was seen as an irrelevance or obstacle in the attainment of such solutions (Sharot, 1976; Goldscheider and Zuckerman, 1984).

The ideologically secularist Jewish movements attracted only a minority of Eastern European Jews, but a number of the secularists joined the mass migration to the West beginning from the 1880s and transplanted their socialist, nationalist, and Yiddish cultural movements to those communities. In the United States, the secularist movements of these Eastern European immigrants continued to find support among the second generation in the years between the two world wars; secularist ethnic identities remained the preference of a minority, but antireligious Zionists, secularist Yiddish culturists, and a number of anarchist, socialist, and communist Jewish organizations could still be found (Glazer, 1957).

Secularist nationalists, especially socialist Zionists from Eastern Europe, were prominent in the first modern waves of Jewish migration to Palestine, and the construction of the national identity of 'New Hebrews' or 'Israelis' involved attempts to make a clear differentiation between nationality and religion. The emphasis on nationality rather than religion was signaled by substituting the 'people of Israel' for 'God' when drawing upon biblical and traditional literature. The dissociation from Judaism in formulations such as 'Canaanites' was intended to contrast between the 'Hebrew' and the 'Jew,' the latter being associated with the negatively evaluated condition of exile.

Both the religious antinational or nonnational Jewish identity espoused by Reform Judaism, and the national, antireligious, or nonreligious Jewish identity of secularist Zionism, were expressions of an acute preoccupation with the boundaries of identity and were cast in highly ideological forms. They were examples of modernist movements in their rejection of the traditionalist religious societies, their conceptions of progress, and their reinterpretations of the Jewish past to legitimize their endeavors and visions of the future. Reform Jews found their values of social justice in the teachings of the ancient Jewish prophets, and secularist Zionists pointed to the Hebrew kingdoms of antiquity as expressions of the primary ties between the people and the land, and the importance of political autonomy. Finding an appropriate link with a distant past, and unburdening themselves of the deadweight of tradition, both Reform Judaism and secularist Zionism presented themselves as carriers of a mission that would bring further enlightenment and freedom in the future (Sharot, 1982).

A number of events and social processes have resulted in the decline of the modernist, ideological forms of the denationalized religious Jewish identity and the dereligionized national Jewish identity. The exclusively religious identity that was given ideological and ritual expression in classical Reform Judaism lost its attraction in the face of vehement racial anti-Semitism, the Holocaust, the achievements of the Zionist movement, the establishment of the state of Israel, and the wars between Israel and Arab countries. The second generation of American Jews tended to be drawn to Conservative Judaism,

which combined religion and ethnicity and provided, in its ritual forms, an attractive middle road between the old-society Judaism of their parents and the Reform Judaism of the more established American Jews. The third and subsequent generations have shifted more to Reform – but this brand of Reform no longer attempts to dispute the national component of Jewish identity, and places greater emphasis on Israel and Zion (Sklare, 1955; Sharot, 1976, 2011).

The Six-Day War accelerated the decline of both the nonnational religious identity among Jews in the Diaspora and the antireligious national identity in Israel. The American Council for Judaism, a Reform offshoot that represented the anti-Zionist position of classical Reform Judaism, virtually collapsed, and in Israel ideological secularism was marginalized by the interpenetration of politics and religion that followed the war (Liebman and Don-Yehiya, 1983). In addition to the Six-Day War and its repercussions, two longer term processes contributed to the decline of a secularist or antireligious Jewish ethnicity, both in the Diaspora and in Israel. One was secularization. Secularist Jewishness had its high point at a time when the religious worldview was beginning to lose its shared, taken-for-granted qualities, but religion still retained a strong influence over a large part of the community. Once the pervasive influence of religion came to be confined to a minority enclave (or a number of enclaves) that rarely impinged on the daily lives of the majority of Jews, secularist Jewishness lost its appeal and was replaced by minimal religiosity. Ideological secularism may appear to have retained some importance in Israel, but it tends to take the form of opposition to the religious establishment and to the political power of the religious sectors, especially the ultra-Orthodox or *haredim*, rather than to religion per se.

Another development that contributed to the decline of the antireligious or nonreligious Jewish identity, especially in the Diaspora, was the decline of ethnic cultural elements (especially the Yiddish language), which in the past provided a cultural basis for nonreligious ethnicity, and the decline of communal and social structures, such as ethnic neighborhoods and industries where Jews provided the majority of both employers and employees. The destruction of Yiddish culture in Eastern Europe and the decline of its remnants in the West undercut the foundations of a Jewish ethnic identity that could draw upon rich cultural resources with little regard to, or in opposition to, religious heritage. Where an all-encompassing religion has lost its strength, and where nonreligious ethnic cultural sources are no longer available, instead of rejecting religious symbols, secularized Jews tend to reinterpret them, extracting their supernaturalist meanings and making them suitable for familial and ethnic celebrations (Sharot, 2011).

Secularization and Fundamentalism

In comparison with the traditional community, in which the great majority observed a comprehensive system of *mitzvot* (religious commandments) that guided their everyday life, Jewish religious observance today is highly selective and fragmented. Rituals that were observed by the great majority in the past, such as following the many dietary laws or the donning of *tephillin* (phylacteries) by males during weekday morning prayers, are observed today only by small minorities. With respect to religious beliefs, a 2008 survey of the American population found that the proportion of Jews who affirm such beliefs as absolute certainty in the existence of God and life after death is considerably lower than that of Christians. There is little difference between American Jews and Christians with respect to joining religious congregations and their social participation in those congregations. However, the proportion of Jews who attend religious services frequently is far lower than that of Christians. About one-half of American Jews attend synagogue on a few occasions, on the high holidays (Yom Kippur and Rosh Hashanah) or for weddings and bar or bat mitzvahs.

The historical identity of Judaism and the Jewish people has meant that a predominantly ethnic Jewish identity can be expressed only through religious symbols and practices, but the symbols and practices that were chosen by secularized Jews are those that relate the individual and family to the themes of the continuation of the Jewish people and its historical emergence and struggles for survival. The rites of passage – circumcision, bar or bat mitzvah, and religious marriage and burial – can be interpreted in this way, and they are observed by the great majority who also signal their Jewish identity by placing the mezuzah (a piece of parchment inscribed with a specific set of verses from Deuteronomy, covered by a protective case) on the doorposts of their homes. The two most popular ritual occasions in all Western communities and Israel are the Seder meal at Pesach (Passover) and the lighting of candles during Hanukkah. The Passover meal is a family occasion, often of the extended family, that celebrates the deliverance from Egypt. More than two-thirds of American Jews and 9 out of 10 Israeli Jews participate in the Passover Seder. Hanukkah commemorates the successful struggle against Syrian-Greek rule and the rededication of the desecrated Second Temple. More than 80% of Jews in both the United States and Israel reported that they lit candles on the nights of Hanukkah. Whereas in the United States Hanukkah, which is close to Christmas, has become the major children's festival, in Israel other ritual occasions (Purim and Lag b'Omer) have become major celebrations that focus on children (with fancy costumes and bonfires, respectively).

Another yearly ritual, fasting on Yom Kippur, is observed by more than one-half of the American Jewish population and by more than two-thirds of the Israeli Jewish population. It is somewhat misleading to compare the American and Israeli populations because Israeli Jews include a large proportion of immigrants and their children from the more traditional communities of North Africa and Asia. A more appropriate comparison is with Israeli-born Jews of European origins, of whom about one-half report that they fast on Yom Kippur. With respect to less popular practices, such as Sabbath observance and separate dishes for milk and meat, the levels of observance are higher in Israel, even when the comparison is confined to Israelis of European origins.

The lower levels of religious observance among American Jews are related to their greater emphasis on voluntarism or choice in the observance of religious customs. American Jews live in a society of religious voluntarism and have adopted the

market system of denominations; among their religious options, they are free to choose to affiliate (or not). The emphasis in Israel is on the protection of Jewish interests by centralized institutions, which include an Orthodox establishment, and the consequence of the almost exclusive state support for the Orthodox is that the Reform and Conservative movements are disadvantaged in competing for the allegiance of consumers of religious services.

American and Israeli Jews attribute different meanings to the term 'religious Jew.' For Israeli Jews, the meaning of *dati* (pl. *datiim*, 'religious') refers to a Jew whom American Jews call Orthodox: a Jews who makes the *Halacha*, the system of religious laws, the basis of his or her way of life. Many American Jews believe that there are different ways of being a religious Jew, and the term can be applied to Reform, Conservative, or even nonaffiliated Jews who may observe only a few religious customs. In recent years in the United States, there has been a growth of those who identify with Reform Judaism or who express no denominational preference, on the one hand, and a growth of those who identify with Orthodoxy, on the other. The growth of the Reform and Orthodox sectors has been at the expense of Conservative Judaism, but the differences among the denominations are viewed as artificial and irrelevant by many lay American Jews who seek a Jewish spirituality that transcends the denominations (Liebman and Cohen, 1990; Cohen and Eisen, 2000; United Jewish Communities, 2003; Levy et al., 2002).

In comparison with surveys of the religious preferences of American Jews, which give denominational options and a 'Just Jewish' option, surveys of Israeli Jews provide the options of *haredi* (ultra-Orthodox), *dati* (religious), *mesoriti* (traditional), and *hiloni* (secular). *Haredi* (pl. *haredim*) is a Hebrew epithet meaning a God-fearing devotee. The term was used in the past to denote any Jew who was punctilious about religion, but in the last 50 years it has been increasingly used to designate those Jews who go beyond Orthodoxy or, a more appropriate term in the context of Judaism, Orthopraxy. *Mesoritim* (pl. of *mesoriti*) accept the Orthodox interpretation of Jewish law as the authentic Judaism, but they admit that they do not observe it fully and are flexible in their observance. They observe those parts of the religious law that they believe are essential to their religious identity. For example, certain *Shabbat* (Sabbath) and *kashrut* (dietary) observances, largely focused on the family, are viewed as essential, whereas regular synagogue attendance is not (Yadgar, 2011).

The most recent comprehensive survey of the religiosity of Israeli Jews, conducted in 2009, found that 8% identified as *haredi* (up from 5% in the 1999 survey), 15% as *dati* (11% in 1999), 33% as *mesoriti* (32% in 1999), and 46% as *hiloni* (down from 52% in 1999). These identities correlate with reported levels of religious observance: *haredim* and *datiim* report that they observe the religious law 'meticulously' or 'to a great extent,' while the *mesoritim* are divided between those who observe 'to a great extent' and those who observe 'to some extent.' Most of the secular who say that they are not antireligious (43% of the total sample) observe the religious tradition 'to some extent,' while most of the secular antireligious (6% of the total sample) say that they 'do not observe the tradition at all.' Far more *Mizrachim*, Israeli Jews of North African and Asian descent, define themselves as *mesoriti* (44% in the 2009 survey) compared with Ashkenazim, Jews of European descent (18%), or those of mixed *Mizrachi*-Ashkenazi parentage (23%). Ashkenazim and those of mixed parentage tend to be more polarized in their religious identifications as either *haredi* and religious or secular (Arian and Keissar-Sugarmen, 2012).

The pattern of a minimal religiosity, largely focused on a few yearly festivals, among a large proportion of contemporary Jews has occurred at the same time as an increase in the ultra-Orthoprax or, as they are called in Israel, the *haredim*. Following World War II, the future of ultra-Orthoprax Judaism had seemed bleak; most of the traditionalist communities of Eastern Europe were destroyed by the Holocaust, and it was expected that the defections to secular society would accelerate in the open societies of the West and Israel. Instead, the last decades of the twentieth century saw a considerable strengthening and growth of the ultra-Orthoprax communities, both in the West and in Israel. By building an enveloping system of socialization and education, separated from the wider society, the *haredim* succeeded in retaining the vast majority of those born within the communities, and, as a consequence of high birth rates, they have grown in numbers. The *haredim* in the United States now represent about one-third of Orthoprax Jewry, and they have spread in the New York area from their established neighborhoods in Brooklyn to *haredi* 'villages' in the suburbs (Heilman, 2006). In Israel, they now constitute about 8% of the Israeli Jewish population and have spread from their centers in Jerusalem and Tel Aviv to an increasing number of neighborhoods and towns.

After the Holocaust, when only a few thousand children were in the *haredi* educational system, the *yeshivot* (higher Talmud learning institutions for males; singular, *yeshiva*) were seen by *haredim* as the principal means by which a Torah-based society could be rebuilt and the youth kept apart from the secular world. Unlike in the former Eastern European communities, the traditional way of life could no longer be taken for granted and had to be constructed on the basis of voluntary communities in which there was a more overt commitment to a strictly religious way of life. Within an encompassing framework, *haredi* males are expected to devote long years to Talmud learning, a way of life that is presented as requiring great effort and devotion and as absolutely essential for the survival of the Jewish people. Removed from the concerns of earning a living and often sheltered from the pressures of families, *yeshiva* students stress stringent interpretations of the religious law. The tradition of written codes has gained in strength at the expense of folk traditions anchored in families and local communities, and younger *haredim* often supersede their fathers in their religious knowledge and strict conformity to the religious laws (Friedman, 1987).

Long years in the *yeshivot* have limited the participation of *haredim* in the workforce, and this is particularly the case in Israel, where government subsidies for the *haredi* way of life are extensive. The traditional rabbinical emphasis on hard work and activism in the world was replaced by interpretations that stressed the role of miraculous events in economic maintenance, the need to abandon profane work in order to worship God, and the devaluation of work as a distraction from the higher calling of study and as an obstacle to salvation. Some *yeshiva* students are now challenging this attitude

toward work and complain that the withdrawal from labor markets has resulted in poverty. This challenge is part of the changes that have been evident in the *haredi* community in Israel since the 1990s. The use of modern technology, especially computers, cellular phones, and DVDs, has given access to a wider knowledge, and various mystical and New Age groups have influenced the community. Some *yeshiva* students wish to be more involved in family life, obtain professional training, join the military, and participate in sociopolitical debates. The religiosity of many *yeshiva* students may be shifting from an otherworldly to a this-worldly piety, but they find it difficult to propose solutions that combine both their religious piety and their material and emotional needs (Stadler, 2009).

The case of Judaism in modern society suggests that the classical thesis of secularization should be modified by attention to polarization between a relatively secularized majority and a neotraditionalist minority. Among the majority of Jews, an often steep decline in religiosity followed the breakup of cohesive local communities, exposure to scientific education and secular beliefs, and an involvement in legal-rational structures. At the same time, the processes of modernization encouraged the countertrend of fundamentalism or neotraditionalism. This was not simply a matter of a rejection of modernity, or important aspects of it, by conservatives or fundamentalists who felt threatened by change. The processes of modernity have themselves provided congenial conditions for the growth and strength of neotraditionalism. In Judaism, it was the reorganization of ultra-Orthopraxy on the basis of voluntaristic communities and reorganized institutions that produced growth, greater militancy, and a radical alternative to the secularized pattern of the majority.

Judaism and Gender

Abstract

This article offers an overview of contemporary research on Jews, Judaism, and gender. It provides a review of scholarly, religious, cultural, and communal efforts to transform Jewish life in light of feminist insights beginning with the second wave of American feminist activism and scholarship. This article addresses the range and depth of these efforts. It also shows how these efforts have forged for a broader vision Jewish community to include others who have been marginalized especially lesbian, gay, bisexual, transgender, and queer Jews in the twenty-first century, and across various Jewish domains.

Building on Virginia Woolf's suggestion that we add a supplement to history as a way of remedying the inequities between men and women, feminist historian Joan Scott calls our attention to the ambiguities within what she has termed "the logic of the supplement." As Scott explains, "women are both added to history and they occasion its rewriting, they provide something extra and they are necessary for completion, they are superfluous and indispensable" (Scott, 1993: p. 241). This contradictory logic is at the heart of what it means to think about gender, Jews, Jewishness, and Judaism well into the twenty-first century. In the context of Jewish communal, religious, and scholarly life, a consideration of women, much less the larger categories of gender and sexuality, has resulted in a radical rethinking of the basic assumptions that have defined every dimension of contemporary Jewish life. On the one hand, the inclusion of women within Jewish life constitutes an expansion of existing narratives. On the other hand, it has become clear that any overview of Jewish life without a consideration of gender and sexuality would be both inaccurate and incomplete.

Late twentieth- and early twenty-first-century Jewish feminist scholarship and activism continue to transform notions of Jews, Jewishness, and Judaism. Key changes in the world of Jewish scholarship are charted by sources noted in the bibliography, including works by Adler, Alpert, Boyarin, Heschel; Hyman, Hyman and Moore, Kaplan; Peskowitz and Levitt, Plaskow, and Prell. Similarly, important discussions of Jewish feminist activism – some of which overlap with the scholarly discussion – include works by Balka and Rose, Beck, Brettschneider, Klepfisz and Kaye/Kantrowitz, Ruttenberg, and Shneer and Aviv. Jewish culture, religion, and history have been profoundly transformed through these efforts, as the simple logic of inclusion has given way to more radical reconfigurations of the Jewish past, present, and future. Jewish feminist activists and scholars have been a part of the broader feminist movement, not only in what is known as the second wave of US feminist activism but also in earlier efforts. Often they have served as leaders in their movements (Klepper, 2013; Hyman, 1995; Kaplan, 1991).

Some Historical Background

As feminist scholars have argued (Kaplan and Moore, 2010; Prell, 1999; Hyman, 1995; Levitt, 1997), the call for inclusion has its origins in the legacy of Jewish emancipation in the West where individual Jewish men – mainly bourgeois – were granted rights as citizens of liberal nation-states. They were emancipated as individuals, not as Jews. By giving up various forms of Jewish communal authority, they came to see themselves reflected in the universal democratic vision of the Age of Revolution.

Although the revolutions of the eighteenth century excluded many people, their vision of universalism offered the promise of emancipation to those who remained disenfranchised within Western culture, including women of the affluent middle classes. Jewish women, whose husbands, brothers, uncles, and fathers had become citizens, began to ask questions about their own status. Using the logic of these liberal revolutions, by the late nineteenth century, Jewish feminists became active in larger women's movements. Together with other women they fought for the right to own property and the right to vote (Klepper, 2013; Hyman, 1995). Such struggles also inspired them to challenge various inequities within Jewish communal life. One result was the dramatic increase in the number of American Jewish women attending synagogues for public worship and the abandonment of gender segregation in seating. By the 1970s, Jewish women used notions of liberal justice and equality to demand their inclusion in all aspects of communal worship. By arguing that specific Jewish communal practices either excluded women or treated them as inferior to men, they demanded their rightful place on the *bema* (the platform with the reading desk at the front of the synagogue), reading torah and leading prayer services. In these ways, they were able to critique the masculinist bias of traditional worship. This liberal critique has expanded to include Jewish social and communal practices, from religious observance to the various fields of Jewish Studies scholarship, although the glass ceiling and powerful inequities in pay and advancement continue to mark organized Jewish communal life and its various institutions (Bronznick et al., 2008).

The growing presence of Jewish women and attention to issues of gender and, increasingly, sexuality have occasioned the rewriting of Jewish history and the rereading of classical Jewish texts in the various subfields of Jewish Studies (religion, literature, history, sociology, political science, and language study) as well as a resurgence in Jewish cultural production including visual art, poetry, fiction, film, music, and dance.

Scholars have used gender analysis to rethink, for example, the gender-segregated spaces of Eastern European Jewish life,

bringing into focus the ingenuity of Jewish women (Parush, 2004). Increasingly, scholars and writers are also addressing the rich gendered histories of Mizrahi – Middle Eastern and North African – Jewish life, and their diasporas (Khazzoom, 2003).

Jewish feminist politics and scholarship, echoing larger scholarly and political trends, has opened up space for serious examination of lesbian, gay, bisexual, transsexual, and queer (LGBTQ) issues in Jewish life, in Jewish texts, and in Jewish ritual and communal practice – perhaps most overtly in the ordination and investiture of LGBTQ people as rabbis and cantors and in the performance of Jewish wedding and commitment ceremonies.

Jewish Religious and Communal Life

In Jewish worship, these changes have been palpable, including a transformation in the language of prayer. Not only is there now gender-inclusive language but also whole new liturgies take account of the experiences of Jewish women (Falk, 1996; Adler, 1998). By the same token, the life experiences of LGBTQ people in the Jewish community have received increasing attention (Drinkwater et al., 2009). Since the 1970s, in increasing numbers of Jewish communities, women are engaging in once restricted religious practices. They are chanting sacred texts, participating in worship services, and receiving honors once granted only to Jewish men. They are leading communal worship as rabbis and cantors (Nadell, 1998). They are also becoming presidents of congregations and Jewish religious organizations. Although many of these efforts remain contested, especially among various Orthodox Jewish communities, among liberal Jews, in Reform, Conservative, Reconstructionist, and Renewal communities, the inclusion of women in all of these realms, including their role as rabbis and cantors, are now very much established practices, especially in the United States. Even among certain Modern Orthodox communities, these roles and practices are changing. Likewise, the growth of Orthodox Jewish feminist prayer groups, study centers, conferences, and the creation of women rabbinic interns throughout the 1990s all attest to the growth of an Orthodox Jewish feminist movement (Greenberg, 1981). Even within ultraorthodox communities, women are reclaiming the rituals of family purity, for example, as attractive Jewish practices for women (Fader, 2009; El-Or, 1994).

In the twenty-first century, formerly marginalized Jews especially gender and sexual minorities and LGBTQ communities, but also disabled Jews, have been granted increasing inclusion. Jewish women and more open LGBTQ Jews are also a part of passing on Jewish religious traditions through the work of Jewish education. Since the nineteenth century, Jewish women have played an ever-increasing role in the education of Jewish children in what had been an exclusively male domain. Women are more often running Jewish day schools sponsored by the various religious movements and training day school teachers and administrators in graduate programs in Jewish education. Among liberal Jews, women are playing an important role in the education of future rabbis and cantors. The number of women on the faculties of the Conservative, Reform, and Reconstructionist rabbinical colleges is growing. Jewish women are also taking on leadership roles as administrators at these institutions; many have come out as LGBTQ people as they serve in these capacities. In all of these realms, there is a growing commitment to include women and LGBTQ Jews in the vital life of Jewish religious practices and Jewish communal life more broadly understood (Prell, 1999). Jewish women are taking on a variety of leadership roles both in North America and in Israel, running Jewish agencies, social service organizations, and federations, although they continue to earn less than their male peers (Bronznick et al., 2008).

In the late twentieth century, feminists made substantial contributions as rabbis, lay leaders, activists, and scholars (Alpert, 1997; Alpert et al., 2001; Shneer and Aviv, 2002; Plaskow, 1990; Beck, 1982/1984/1989; Balka and Rose, 1989). Notions of family, community, and religiosity were powerfully challenged by their strong presence within and outside of organized Jewish communities, leading to more recent and more radical changes. They also challenged the criteria for membership in Jewish congregations and communal organizations, constructing new rituals of recognition such as marriage and commitment ceremonies and events to celebrate "coming out" in a Jewish context. They also joined gay men in demanding that the Jewish community address homophobia and the impact of the AIDS epidemic on Jews, especially as the crisis peaked in North America in the late twentieth century (Balka and Rose, 1989; Shneer and Aviv, 2002).

Jewish Studies

The various fields of scholarship in Jewish Studies have also witnessed the growing presence of women as a precursor to more critical transformations of scholarly practice, particularly in the fields of text study, religion, history, literature, and the various social sciences. Although Jewish women were already active in the academic study of Judaism beginning in the late nineteenth century, the most powerful and dramatic changes came with the second wave of US feminist activism. Feminist scholars have not only added women to the study of ancient Jewish texts, Jewish philosophy, theology, history, literature, and social scientific studies, they have raised questions about both the content of Jewish Studies courses and the ways they are being taught in colleges and universities (Prell, 2007; Diner et al., 2010; Peskowitz and Levitt, 1997; Davidman and Tenenbaum, 1994).

Work on classical Jewish texts, the Hebrew Bible (Levkovitz, 2010; Pardes, 1992), and especially rabbinic literature have changed how these sources are read (Ilan et al., 2007; Labovitz, 2009; Baker, 2002; Peskowitz, 1997; Boyarin, 1997; Hauptman, 1998; Adler, 1998; Biale, 1984). Feminist scholars have not only looked at how Jewish women figure in these texts, they are increasingly raising questions about how gender is produced in these texts and how these visions of gender have become normative. Here reading practices are crucial. As Miriam Peskowitz (1997) notes, such normative texts can and should be read as legal fantasies, following the lead of recent scholarship in critical legal theory; these texts tell us about the desires of those who produced them.

Jewish feminist scholars have also taken on the traditions of Jewish theology, ethics, and philosophy to offer new approaches to these various fields of Jewish religious studies

scholarship (Tirosh Samuelson, 2004; Shapiro, 2003; Adler, 1998; Plaskow, 2005, 1990; Alpert, 1997; Levitt, 1997; Falk, 1996; Weissler, 1998). These scholars not only question the gender of God but the subject of ethical discourse. Who is the person making moral choices, and from what standpoint are these issues being addressed? They also challenge the mind–body dualisms that mark medieval as well as modern Jewish thought and their implications for Jewish women. In Jewish history, feminist scholars have used the incorporation of women to their readings of the Jewish past to rethink some of the grand narratives that have shaped Jewish historical study. By demonstrating the role women played in emancipation and enlightenment, modern Jewish historians have shown us how vital Jewish women were to these transformations in Jewish life (Hyman, 1995; Kaplan, 1991). Jewish feminist historians have also called our attention to the role of Jewish women in assimilation into American culture (Diner et al., 2010; Kaplan and Moore, 2010; Prell, 1999, 2007).

Broader works on twentieth-century Jewish history have also been transformed by accounts of gender. Included in this scholarship are powerful accounts of Zionism as a masculinist national movement (Boyarin, 1997; D. Biale, 1992) as well as a growing body of literature about the role of women in the devastation of the Holocaust (Ofer and Weitzman, 1998; Rittner and Roth, 1993). As Daniel Boyarin (1997) points out, Zionism was a way of remasculinizing the Jewish people. On the other hand, feminist scholars have begun to examine how the experience of genocide was gendered. They point to how and in what ways pregnancy, menarche, menstruation, and motherhood marked Jewish women in the Holocaust. Feminist scholars have also addressed the particular devastation of sexual assault in this context, and spearheaded work on Holocaust memory and its representations (Hirsch, 2012; Levitt, 2007).

Finally, women's historians have called attention to the roles of Jewish women in the ancient past. Not only were they wives, daughters, and mothers, they were also workers. They were dyers and weavers, spinners and artisans alongside men, and they were also communal leaders (Baker, 2002; Brooten, 1982; Peskowitz, 1997; Meyer, 1988). The work of feminist scholars has offered us new evidence of the lives of Jewish women in all these eras of the past. In the social sciences, feminist scholars have called our attention to the role of Jewish women in Jewish communal and political life, including their role in the process of Jewish assimilation. How did they dress themselves and their families or decorate their homes? What did they serve their families for dinner? These are all crucial questions for feminist ethnographers who are re-examining American Jewish assimilation (Diner et al., 2010; Prell, 1999; Kaplan and Moore, 2010; Davidman and Tenenbaum, 1994).

The work in Jewish literature is massive and complex. Feminist scholars have not only discovered heretofore forgotten or unknown texts by Jewish women in various languages including Hebrew, Ladino, Yiddish, Russian, and English (Balin, 2000; Zierler, 2004), they have also offered new accounts of more well-known texts (Fuchs, 1987; Seidman, 1997). Scholars like Seidman (1997) have also asked us to reconsider the relationship between Jewish languages and how gender is used to naturalize the privileging of Hebrew over Yiddish. As she explains, like the relationship between husband and wife, Yiddish, the language of daily life, was subservient to Hebrew, the masculine language of prayer and traditional Jewish study.

Jewish Cultural Production

Recent works of feminist art and literature have not only built on the work of Jewish scholars in a variety of fields, they have also used popular and material culture to offer critical perspectives on Jewishness as a cultural and ethnic as well as a religious identity. Some works highlight the absence of Jewish women from certain forms of religious or cultural production, like the reading and writing of sacred texts (Aylon, 2012). Others have used these artifacts including texts to create new theatrical or cinematic productions on Jewish women. Since the 1970s, there has been a growing body of Jewish feminist literature especially by Jewish lesbian feminists (Alpert, 1997; Alpert et al., 2001; Beck, 1982/1984/1989; Brettschneider, 2006; Klepfisz and Kaye/Kantrowitz, 1986/1989; Ruttenberg, 2001). These writers often focus on Jewishness as a cultural and political and not a religious practice. More recent efforts have included the reclaiming of klezmer music and the resources of Yiddish film for new cultural production.

In the arts, the inclusion of women and queers has expanded the realm of Jewish cultural production in the United States as well as Israel. Increasingly, Jewish women and LGBTQ Jews are playing an active role in these efforts by creating new works, sponsoring exhibits, and participating in various forums to present feminist and queer artistic works to a broader audience (Aylon, 2012; Antler, 1998; Prell, 1999). Here Jewish museums have become a crucial site for new forms of Jewish feminist and queer cultural production (Shneer and Aviv, 2002, 2005).

Future Prospects

Although Jewish women are a part of Jewish communal life, now more than ever, there is much more work to be done. Efforts to make explicit the inequities at the heart of many Jewish communal practices, much less the exclusion of women from sacred texts and the problematic roles they do have when they are included in these texts, all demand ongoing critical examination. Such efforts have bolstered, challenged, and enhanced a growing awareness of the many other forms of exclusion that haunt Jewish life, not only in terms of gender and sexuality but also disability. Among Jewish feminists, the idea of giving up these traditions is too simple. Although they are critical of these texts, they continue to claim them and try to find ways of forging new and more powerful relationships with these legacies. Jewish women and LGBTQ Jews are carrying out this labor as university scholars, day school teachers and administrators, cantors and rabbis, and poets, artists, musicians and filmmakers, and as bloggers.

Judges

José J Toharia, Metroscopia, Madrid, Spain

Abstract

As the official specifically charged with the administration of the law, the figure of the judge has adopted a varied number of shapes in different times and societies. However, the multiplicity of historical experiences can be reduced, for analytical purposes, to a few basic typologies (or 'ideal types,' in Weberian terminology), which are briefly discussed. Particular and more detailed attention is given to the two specific configurations of the judicial role (i.e., the Civil Law and the Common Law judge), which clearly predominate in most contemporary societies.

A judge is a public officer whose role is to administer the law in a Court of Justice impartially and independently. Judicial independence is instrumental to judicial impartiality, since only an independent judge can be expected to be fully impartial: hence the configuration of the role as that of an officer within some governmental structure, a measure originally meant to provide protection against pressures from the confronting parties (Shapiro, 1981). However, while the official status of the judicial function may provide protection against the parties it may also facilitate pressures and influences from those to whom the judge owes the office. In some highly infrequent cases (such as early Roman Law) the judge is freely elected by the parties who commit themselves to abide by his decisions. However, in most historical instances the judge's authority and binding capacity is independent from the will of the involved parties and derives from the backing granted to judicial actions by the political system. This creates a direct link between the legitimacy of judicial institutions and the type of legitimacy of the prevailing form of political government. Judicial impartiality can thus be expected to be reasonably guaranteed only under strict democratic rule, one of the basic requisites of a democratic polity being the existence of an effectively independent judiciary.

Officially empowered to determine in a binding way with which of the contending parties lies the legal right, the judge constitutes a key, central figure in all legal systems, past or present. However, the judge is but one among other possible conflict-solving institutions. Rather than as a discrete, fully differentiated category, he or she can be better understood as one end of a continuum that would run: *go-between*, *mediator*, *arbitrator*, and *judge* (Shapiro, 1981: p. 3). All those roles require impartial implementation but differ in the degree of formalization and depersonalization in presiding over the relation with the contending parties. The *go-between*, who operates on a pure consent basis, represents the more informal, face-to-face and equity-oriented end of the continuum; the judge, professionally trained, vested with official authority and required to lack all personal acquaintance with the parties, occupies the opposite end.

As societies become more complex and differentiated, and as the state-controlled legal system increases its centrality in social life, the role of the judge gains predominance. However, the other conflict-solving roles do not disappear; instead, they subsist as alternative – and usually very active – instances. The continuum can be thus perceived as a cumulative process, allowing for the emergence of progressively more complex and formalized agencies of conflict resolution that coexist with the preceding ones (*see* Dispute Resolutions in Economics).

Types of Judges

A basic typology of judges can be attempted from the combination of three factors that shape judicial roles. First, *the type of legal system* within which the judge operates: a basic distinction can be made between Western legal systems (comprising both Common Law and Civil Law systems), and all other types of systems, such as *Far Eastern* (Chinese and Japanese), *Religious* (Islamic or Hindu), or *Socialist* (see Zweigert and Kötz, 1998). The second factor is the type of political legitimacy underlying the body of laws to be applied, and consequently underlying the political system, which upholds those laws (Weber, 1947). Finally, the basic function that is attributed to the judge: a basic distinction can be made between authoritative adjudication and mediating arbitration. The following classificatory scheme results.

Democratic Judge

A type of judge who adjudicates cases applying rules of general validity, enacted by duly elected representatives of the citizenry. This type of judicial system corresponds to representative democracies (legal-rational type of domination in Weberian terms). There are two possible formats for the *democratic* type of judges: Common Law and Civil Law.

Traditional or Predemocratic Judge

A predominantly arbitrating, conciliatory type of judge who applies norms embodying a traditional legacy, contained in religious, moral or ethical codes, or in local customs, *mores*, or folkways. This type of judge would correspond to the Weberian category of 'traditional' political domination. Several classical types of judicial roles can be included within this category: the historical Islamic *Qadi* Judge (who attempts conciliation – if and when the compromise does not permit what is forbidden or does not forbid what is permitted by the religious law – and who adjudicates on a case-by-case basis according to equity); the traditional Far Eastern Judge (Chinese or Japanese), more concerned with mending and preserving social harmony and

equilibrium than with legal arguments or questions of individual rights; and the African or Native American type of customary judge.

Nondemocratic Judge

A type of judge corresponding to autocratic political situations where the norms to be applied may be claimed to express the will of the people, *but as interpreted and elaborated by an autocratic ruler* (or ruling body), self-appointed as exclusive, natural spokesman for the collective will, and as such above any need for elective confirmation. This third situation could be associated with Weber's concept of *charismatic* rule.

Increasing Convergence

This threefold typology provides basic global models or *ideal types* but is not meant as a description of real contemporary judicial systems. The judicial systems of the more economically developed and more democratically stable countries would generally fit well into the first ('*democratic judge*') category. Most other countries striving in many cases to consolidate modernized and democratic polities, and as such immersed in transitional situations, represent mixed, intermediate stages. However, the generalization can be made that as processes of economic, social, and cultural globalization take place at a world-scale, and as political democratization and the rule of law tend to become increasingly undisputed, universal goals, the tendency can be detected in most developing countries toward the adoption of judicial systems parallel to the two models of justice prevailing in stable democracies (predominantly, the Civil Law type of judicial system). In quite a few cases this has implied some degree of *denaturalization* of the imported model, since the modern Civil Law (as well as the Common Law) type of judge is designed to function under democratic conditions. Certainly this was not always the case: both systems (Civil and Common Law) had emerged and consolidated well before the modern idea of the rule of law had even begun to develop. But their current configuration results from the substantial redefinitions they both experienced in the wake of the democratic revolutions of the eighteenth century.

Judicial Systems in Developing Countries

Purely customary judicial systems have become a rarity of mainly anthropological or historical interest. By 1990, all Francophone African countries, with the exception of Cameroon, had suppressed all types of customary courts, establishing a state system of courts of the Civil Law type (Mangin, 1990). In Anglophone Africa, customary courts are still allowed to exist in most countries but as marginal institutions, their decisions in any case being appealable to state courts, mostly modeled along Common Law lines (Coldham, 1990). One of the most conspicuous instances of Far Eastern traditional-type of judge, the Japanese, is now extinct and has given way to a Civil Law type system of justice, with some elements of Common Law (Oda, 1992).

Apart from China, one of the few remnants of the 'socialist' category of judicial system, most traditional judicial systems are experiencing assimilation to the Western models. In India, where a process of *hybridization* gave birth to 'Anglo-Muhammadan' and 'Anglo-Hindu' law (Zweigert and Kötz, 1998: 310 and 318), these bodies of law are administered by state judges in Common Law style.

In the case of the Islamic world a distinction has to be made between: (1) countries, which in the wake of Islamic fundamentalist revolutions reorganized as Islamic Republics and which would still fit into the traditional/religious category of judicial systems; and (2) countries which though experiencing, in different degrees, a trend toward the re-islamization of social, legal, and political institutions still can be considered to maintain a predominantly secular state-courts system created in most cases in the 1950s and 1960s, along the Civil Law model (Botiveau, 1994).

Civil and Common Law Judges

The two types of judicial systems increasingly predominant in the contemporary world (Civil and Common Law) share a basic common, albeit distant, root: Roman Law, Justinianean and Classic, respectively (van Caenegem, 1988). Their historical development led to differing legal and judicial traditions: Common Law is "judge-made law, that is to say (consisting of) rules to be collected from the judgments of the courts" (Dicey, 1961/1885), whereas codification stands out as the basic identifying feature of Civil Law (Merryman, 1969). But they both embody what seems to be the final stage of the centuries-long process of evolution of the Western legal tradition. As pointed out by Berman (1983) the emergence of Canon Law (which gave rise to the first full legal system), the Protestant Revolution (which secularized the legal world), and the English Revolution (which established the supremacy of Parliament) paved the way for the two versions of democratic judicial systems predominant today and brought about by the American (1776) and French (1789) Revolutions. As democratically reborn judicial systems, both the Civil Law (as reshaped by the French Revolution) and Common Law (as amended on American soil) share a similar contextual prerequisite for their adequate operation: the existence of the rule of law within a pluralistic, representative democracy.

However, both systems diverge in the way in which they attempt to keep the organization of justice in line with the commonly shared dogma of popular sovereignty. The variant of the Civil Law, which originated in the French Revolution was basically intended to prevent judges from interfering with the popular will as expressed in the statutes enacted by duly elected representative bodies – a reaction against the preeminence of *Parlements* under the *Ancien Régime*. In the new, democratic situation the judge had to be just 'the mouth of the law,' in Montesquieu's words. Only from an unswerving application of democratic laws would the judge acquire a democratic character. Contrarily, the main purpose of the judicial system established by the 1787 American Constitution was to make the judge an essential element of the tripartite system of checks and balances that the new democratic polity was intended to be – Congress, the President, and the Judiciary. To this effect,

the judge had to apply the new statutory law democratically enacted (which should be given priority in cases of collision with judge-made law); at the same time the judge was empowered to insure that statutes passed by ephemeral, temporary majorities would not contravene the basic covenant contained in the 'supreme law of the land' (i.e., the Constitution) (*see* Judicial Review).

As a consequence, two clearly differentiated models of 'democratic justice' crystallized. On the one hand, the Common Law judge, as watchperson of the Law, that is, of the "patchwork quilt of legislative provisions held together by thread woven out of general principles and sewn by the judges" (Bell et al., 1998: 5), performs his functions with a basic policy-implementing orientation (Damaska, 1986) predominantly within an adversarial system. On the other hand, the Civil Law judge, as a specialized anonymous civil servant, decides the cases brought to him applying a body of written legal norms – assumed to provide a complete and coherent repertoire of solutions; his functional orientation is inquisitorial and conflict solving. Intended to be a system of justice rigidly respectful of the popular will, the Civil Law system turned out in practice to be a machinery of justice administration insulated from politics. Although this sounds favorable, what it means is that the Civil Law model of justice, devised for a democratic setting, proved equally functional when the overall political system ceased to be democratic. The system had been designed to provide a dutiful application of the laws in force, whatever their nature, not to scrutinize their legitimacy or interpret their contents. A change from democracy to autocracy meant no difference for the internal logic of the system, which could continue operating practically unchanged. The cases of Italy, Germany, and Spain in the twentieth century, to mention but some particularly conspicuous cases where breakdown of democracy, autocratic rule, and return to democracy did not entail any proportionally correlative reorganization of the judicial system and even just marginal changes in the composition of the judiciary provide telling examples (Toharia, 1975). This unintended political *floating* ability and adaptability of the Civil Law model explains the successive attempts to amend its original late-eighteenth-century design in order to reinforce its original democratic structure. The increasing importance given to *jurisprudence* (or binding judicial interpretation of norms), a word which Robespierre wanted to see removed from the French vocabulary; the gradual introduction of varying forms of judicial review (in most cases in the form of Constitutional Courts) largely under Hans Kelsen's influence in the 1920s and 1930s; the practical disappearance of the inquisitorial principle (which in its most classic and pure form has become now a rarity likely to disappear soon, as is the case of Spain); and new forms of judicial activism (Guarnieri and Pederzoli, 1996) are clear examples of the reorganization that the original structure has been experiencing. In a sense, these changes reflect an increasing pattern of convergence between Civil and Common Law models (Cappelletti, 1989), a convergence that goes both ways: a telling example is the impact that the legal system of the European Union is having on the legal and judicial practices of the United Kingdom, which has meant substantial and gradual redefinitions of some basic Common Law features (White, 1999).

The Expanding Power of Judges

Most democratic countries have experienced in recent years a process of *judicialization* of their political life, with "the infusion of judicial decision-making and of court-like procedures into political arenas where they did not previously reside" (Vallinder, 1995). This has produced an unprecedented expansion of the power and influence of judges, especially in Civil Law countries where judges have traditionally kept a very low profile in public affairs. Basically this process has resulted from the combined effect of two major trends: on the one hand, an increased judicial activism in areas such as the control of governmental decisions and the protection and assertion of individual rights; on the other hand, the tendency among political decision makers to defer to the Courts of Justice the resolution of issues with a highly divisive and conflictive potential. This second pattern has been a special cause for concern as it may imply a weakening of the legitimacy of representative institutions. If judicial adjudication and political decision making are perceived not as a dichotomy but as the two ends of a scale (that would run from total majoritarianism to total government by judiciary) what can be concluded is that most democratic countries seem to have experienced over the last two decades a relative swing toward the government by judiciary end of the scale (Vallinder, 1995).

The Selection of Judges

A key element in the configuration of any judicial system is the way in which judges are selected. An ideal system of judicial recruitment should allow for: (1) the selection of competent and qualified persons; (2) through mechanisms unlikely to impair their impartiality and independence while in office; (3) making room for mechanisms of discipline, evaluation, and accountability of the judicial personnel; and (4) aiming to create a judiciary as representative as possible of the social body (in terms of ideology, social class, gender, race, religion, or other relevant social attributes). These four ideal requirements are obviously difficult to meet and most existing systems of judicial recruitment attempt to achieve them through a wide variety of arrangements – which probably explains why "no other governmental official is selected by so many different methods" as the judge (Stumpf, 1998: 135).

A basic, preliminary distinction can be made between *professional* and *bureaucratic* systems of selection (Guarnieri and Pederzoli, 1996), corresponding respectively to Common Law and Civil Law judicial systems. The *professionalized* selection looks for judges among already experienced, practicing lawyers, which produces an older body of judges who have relatively short tenure as judges. (On mechanisms of selection see *Judicial Selection*). By contrast, the *bureaucratic* system of selection prevailing in Civil Law systems allow for much longer judicial careers: from an average entrance age barely around or below 30, to compulsory retirement around age 70 or even 75. The system is not meant to select mature, experienced lawyers and make them judges but rather to select young law graduates, without any previous legal practice, and prepare them for a lifelong career in the judiciary. The sense of achievement within the legal profession and the social aura and moral

auctoritas that characteristically go with the image of the Common Law judge, is lacking in the Civil Law counterpart.

Judges' Social Representativeness

As professionals called to perform a highly specialized task implying extensive legal training, judges have tended historically to be recruited among members of educated, well-to-do sectors of society. This has resulted historically in an almost universal double structural bias within all Judiciaries: a *class bias* (middle- to lower-class people, as well as people from minority groups, were likely to be strongly underrepresented) and a *gender bias* (women were particularly likely to be strongly underrepresented, as a result of the late recognition of their rights to equal education and equal access to professional life). A third, additional bias might even be said to have characterized the judiciary traditionally: a *conservative bias* (as suggested originally by Max Weber, who pointed to the inherent conservative implications of legal reasoning and thence its more likely appeal for conservative-minded persons). As a result women, members of minorities, persons of lower-middle or working-class origin, and people with ideologically progressive orientations were only rarely found within judiciaries.

To a large extent, all these biases seem to be gradually fading, as educational systems have become more inclusive and affirmative action programs have promoted higher levels of social equality. As for the social origin of their members, Civil Law judiciaries have been traditionally less elitist than their Common Law counterparts: in countries such as France, Italy, or Spain most judges tended to come from rural and middle- to lower-middle class families whereas in the US or in the United Kingdom urban upper or upper-middle class origin usually prevailed. But in both cases the presence of judges with lower or working-class origin was practically nil. This situation is changing substantially in both systems as judiciaries gradually become more representative of the prevailing social structure (Toharia, 1987). The data in the table (see Inset) reflect the gradual increase of social pluralism within most judiciaries over the last three decades. The change is particularly perceptible with respect to the increased presence of women, especially in Civil Law systems. The universalistic, competitive nature of the *bureaucratic* process of selection (generally based purely on personal performance in public entrance examinations, which leaves less room for blatant discrimination), and the fact that it takes place at a much earlier point in professional life seems to account for this seemingly more advanced degree of *feminization* of most Civil Law judiciaries. The presence of women within the judiciary may be said in any case to have well passed beyond the 'tokenization' phase, and to be becoming a fully institutionalized pattern. Even in Muslim countries such as Tunisia, in spite of the controversy reopened by the religious fundamentalists' questioning of the eligibility of women for judicial office, in 1994 one out of every four judges was a woman (Botiveau, 1994). To a somewhat lesser degree, the presence of racial and religious minority groups within the judiciary has also increased. As for the *ideological bias* the issue seems to have lost much of its former intensity. In Common Law countries, appointment or direct election of judges on the basis of their ideological orientation is perceived as a legitimate way of creating a bench that 'looks like the country.' In Civil Law countries, where judicial systems are supposed to be person-proof, the scant data available indicate nonetheless that the ideological composition of the judiciary tends to reflect quite closely the ideological pluralism prevailing in the global society (Toharia, 1987). The pattern of affiliation to the ideologically oriented unions of judges existing in countries such as Italy, France, or Spain provides an additional evidence of such pluralism.

How socially representative is the Judiciary?

Women and other social groups within the Judiciary. Some selected historical landmarks

Date	*Country*	
1835	USA	First Roman Catholic appointed to the Supreme Court (Roger B. Taney)
1916	USA	First Jewish-American appointed to the Supreme Court (Louis Brandeis)
1961	USA	African-American judges represent 0.8% of all state and federal judges
1962	UK	First woman appointed as County Judge (Elizabeth Lane)
1965	UK	First woman appointed to the High Court Bench (Elizabeth Lane)
1967	USA	First African-American appointed to the Supreme Court (Thurgood Marshall)
1967	Tunisia	First woman admitted into the Judiciary
1977–80	USA	President Carter's positive action program results in the appointment of 100 women, African-Americans and Hispanic-Americans to the Federal Bench.
1979	UK	England's first Sikh judge appointed
1979	California, USA	Governor Brown appoints America's first openly homosexual judge
1980–81	USA	3.1% of all US State Supreme Court justices are women
1981	USA	First woman appointed to the Supreme Court (Sandra Day O'Connor)
1981	California, USA	Governor Brown appoints first openly lesbian judge

(Continued)

How socially representative is the Judiciary?
Women and other social groups within the Judiciary. Some selected historical landmarks

1986	USA	First Italian-American appointed to the Supreme Court (Antonin Scalia)
1989	Germany	18% of all judges are women (vs 3% in 1960)
1990	The Netherlands	28% of all judges are women (vs 11% in 1973)
1992	Georgia, USA	First African-American woman appointed to the Supreme Court of a former Confederate State
1992	Costa Rica	42% of all judges are women
1992	Buenos Aires, Argentina	26% of all judges are women (vs 11% in 1985).
1993	USA	10% of all federal judges are African-Americans
1993	USA	3.3% of judges in all levels of the US Judiciary are African-Americans
1994	Tunisia	23% of all judges are women
1994	Venezuela	First woman ever appointed as Chief Justice of a country's Supreme Court (Ms. Cecilia Sosa)
1994	UK	Percentage of women in the different levels of the British Judiciary: Heads of Division: none; Lords Justices of Appeal: one out of 32; High Court Judges: 6%; Circuit Judges: 6%; District Judges: 10%.
1995	Italy	41% of all judges are women
1996	France	47% of all judges are women
1996	USA	Of all judges within the Federal Judiciary, 9% are African-American, 4% Hispanic-American, 0.6% Asian-American and 0.2% Native American. These minority groups add up to 13.8%, vs 4.9% in 1976.
1996	USA	Within the Federal Judiciary, 17% are women (vs 1% In 1976 and 9% in 1989). During President Clinton's first administration (1992–96) 31% of all appointments to the Federal Bench were women (as compared with 0.4% under Nixon, 16% under Carter, 8% under Reagan and 19% under Bush), and 33% to members of minority groups.
1999	Spain	34% of all judges are women, vs 12% in 1987. Among the last class of new judges selected, 58% are women.
2010	USA	Upon the confirmation of Associate Justice Elena Kagan, the US Supreme Court counts three women among its nine members for the first time in history.
2012	USA	33% of all active district (or trial) court judges are women
2012	USA	President Obama establishes a record, adding 72 women judges to the Federal Bench, the most ever appointed by a President in a single term. President Clinton had a larger number of women confirmed as federal judges during his two-term presidency (111).
2012	European Union	34% of all supreme court judges in EU member states are women. This percentage varies very substantially between the different countries the differences in this proportion
2012	USA	32% of the 164 active judges sitting on the 13 federal courts of appeal are women
2013	European Union	18 of the 47 judges (38%) of the European Court of Human Rights are women

Judicial Behavior

Abstract

How do judges decide cases? This article reviews the myriad factors that may influence judicial behavior, including law, ideology, and strategic behavior, and argues that no single factor can explain judicial decision-making; instead, the choices justices make are influenced by a combination of factors. The article concludes with some suggestions for future research that acknowledges individual-level variation in the effects of these factors.

What factors influence a judge's decision? To what extent are judges influenced by law, ideology, and politics as they write their opinions and decide cases? Refining the answers to these questions has been the major project of judicial scholars for decades. For many years, scholars leaned upon separate models of judicial decision-making that privileged singular explanations, such as legal or attitudinal factors, as the dominant force underlying judicial decisions. Now, however, scholars have come to the consensus that judicial decision-making is influenced by a variety of legal and extralegal factors, a view summarized well by Gibson (1983): "judges' decisions are a function of what they prefer to do, tempered by what they think they ought to do, but constrained by what they perceive is feasible to do" (9).

This article reviews the political science literature on judicial behavior, with a particular attention to the varying factors that research indicates affect judicial behavior. In particular, the article discusses the relationships between a number of factors, including law, personal preferences, other judges in the legal system, Congress, the executive branch, organized interests, and the public, and judicial behavior. The article concludes with some suggestions for future research that acknowledge individual-level variation in the effects of these factors.

Law

As any elementary school student learns, the task of judges is to interpret the law and to apply prior rulings to the present case. Levi (1948) describes this classic model of legal reasoning and judicial decision-making: "similarity is seen between cases; next the rule of law inherent in the first case is announced; then the rule of law is made applicable to the second case" (2). In other words, judges decide cases through a process of analogical reasoning; they wade through the body of precedent, find the cases most similar to the present one, and then apply the law from those past and similar cases to the facts of the case at hand. But, in practice, to what extent do legal factors affect the outcomes of cases? As such, a natural starting point for understanding judicial behavior is the law.

Conceptually, one can view law both as a constraint and an opportunity for judges (Hansford and Spriggs, 2006). On the one hand, clear precedent bounds judicial behavior by forcing judges to decide a given case in a particular way while also prohibiting judges from deciding cases in other ways. A trial court judge, for example, lacks the discretion to sentence a jaywalker to death. On the other hand, law provides an opportunity for justices. If lower court judges are bound by the decisions of higher court judges, as they are in common law systems, then high court judges have an opportunity to write their policy preferences into law by crafting law that must be followed by lower court judges. Thus, law provides an opportunity for high court judges to chisel their policy preferences into law that binds the decisions of future judges.

One of the earliest attempts to quantify the influence of law on the decisions of judges is Segal's (1984) study of U.S. Supreme Court search and seizure cases 1962–81. Segal coded a variety of facts for each case (e.g., the presence of a warrant) and then used those facts to predict whether the Court would find the search to be a reasonable one. His results indicate that one can predict the Supreme Court's finding about the reasonableness of a search, given only information about legal factors; this provides strong evidence that law plays some role in structuring the decisions of judges.

Of course, not every case fact is equally important; oftentimes, legal rulings give prominence to particular legal factors. For example, the U.S. Supreme Court's ruling in *Adarand Constructors, Inc. v. Peña* (1995) held that the constitutionality of race-based classifications (a case fact) must be decided using strict scrutiny (a legal standard). In other words, if a judge is deciding a case in which a classification that treats people differently based on their race is at issue, then that judge is bound to apply a particular legal standard (strict scrutiny) in his/her decision. If legal considerations are at the forefront in judicial decision-making, then case facts or standards of review should have differential effects before and after a Court ruling that codifies their importance. This is the theory that Richards and Kritzer (2002) test with regard to content-neutrality doctrine in free expression law. They present persuasive evidence that jurisprudential regimes condition judicial decision-making by changing the set of facts that are deemed important for judges to consider when they decide a case in a given area of law while implicitly giving less weight to other case. Still, other scholars have cast doubt upon these findings, suggesting that jurisprudential regimes play only a minor role in structuring the choices justices make. However, the weight of the evidence about legal factors on judicial decision-making indicates that law does play an important, albeit partial, role in structuring the choices that judges make.

Ideology

Strictly legal explanations have a major drawback: they struggle to explain nonunanimous decisions. If legal factors are the predominant base of judicial decision-making, then nonunanimous decisions are 'mistakes' brought about by judges who misinterpret the law. Yet, while unanimous decisions represent the plurality of the decisions of the U.S. Supreme Court (a fact that is often overlooked), a significant number of Supreme Court decisions invite the dissent of one or more judges, particularly in the Court's most political and salient cases. To that end, attitudinal explanations of judicial behavior provide a second factor that can explain the dissenting behavior of judges.

The clearest statement of ideological influences in judicial decision-making comes from Segal and Spaeth (2002), who formalized what they called the attitudinal model of judicial decision-making. They write: "[t]his model holds that the Supreme Court decides disputes in light of the facts of the case vis-à-vis the ideological attitudes and values of the justices. Simply put, Rehnquist votes the way he does because he is extremely conservative; Marshall voted the way he did because he is extremely liberal" (65). In other words, these attitudinalists argue that the personal political values of judges affect their legal decisions.

Segal and Spaeth present a variety of statistical evidence to demonstrate that attitudes have an independent effect on the decisions of judges. First, they return to Segal's (1984) finding that legal factors can predict the Court's eventual finding of the reasonableness of a search, but they go a step further and determine whether, once one considers attitudinal explanations, legal factors still can predict the reasonableness of a search. They find that judicial ideology has an independent and unique effect on judicial decision-making even after the effects of case facts on judicial outcomes are considered. Second, they examine the effects of the norm of *stare decisis*, the legal principle that states that past decisions must be followed when deciding a current case, on the decisions of justices. If law, and not ideology, is the predominant force behind judicial decision-making, then judges who were in dissent in a previous case should be constrained by the precedent set in that past case and vote differently when the issue comes before the court again. Yet, Segal and Spaeth present a variety of evidence suggesting that judges tend to support their initial position, rather than the precedential position, when an issue comes before the court a second time. This finding further bolsters their theory.

This evidence suggesting that judges' personal preferences influence their decisions creates a problem: how does one know what the personal preferences of judges are? After all, the ability of scholars to parse the effects of ideology from the effects of law is limited by their ability to construct a measure of ideology that is both valid and reliable. As a result, a major strand of research over the past 30 years has sought to measure the ideology of judges.

In one of the first attempts to quantify judicial ideology, Pritchett (1948) sought to determine whether Roosevelt's appointees voted differently than those justices who were on the Supreme Court when Roosevelt took office. To this end, Pritchett took a simple, but powerful, approach: he simply counted the number of times that Justice X cast a vote that agreed with Justice Y and then calculated the percentage of cases in which Justice X agreed with Justice Y. His analysis of the Roosevelt court indicated that Roosevelt's appointees were more likely to vote with each other than they were to vote with other president's appointees.

While Pritchett's method was ingenious because it relied upon no assumptions about the ideological direction of the Court's decision, scholars have also measured ideology by aggregating the votes of justices and assigning each vote a liberal or conservative direction. Scholars then use the justice's aggregated liberal or conservative voting in one or more past terms to predict their votes in future cases. However, reliance on justices' votes as an explanatory factor in a model that seeks to predict justices' votes presents a circularity problem: scholars are trying to predict a quantity of interest by using that same quantity of interest as a predictor.

With the circularity problem in mind, scholars have searched for a measure of judicial ideology is valid and does not rely on justices' votes to produce the measure of ideology. With this in mind, a wealth of literature has relied (and, in some cases, still relies) on the party of the appointing president as a measure of judicial ideology. The idea behind the measure is a simple one: if one knows who sought to place a judge on the bench, one can guess accurately about the personal policy preferences of that judge. This measure relies on a major assumption, namely that presidents attempt to cement their legacy by appointing judges who share their views to the U.S. Supreme Court. Still, party identification has been widely used (and is still commonly used today) as a measure of judicial ideology, particularly for lower federal courts in the United States.

Of course, even presidents from the same party vary in their personal views, and the fact that Senatorial confirmation is required of the U.S. federal judges means that any presidential nominee to the bench must be approved by the Senate suggests that presidents may not always be able to place their ideal nominee on the bench. If this is the case, then presidential party is an overly simplistic measure of judicial ideology. To this end, Segal and Cover (1989) relied upon newspaper editorials discussing the views of nominees to the U.S. Supreme Court to create an indicator of judicial ideology that is not dependent upon the eventual votes of the nominees once they take their seat on the Supreme Court. However, because these editorials come at the time of a justice's nomination to the Court, the Segal–Cover scores measure a justice's perceived ideology at the time they were nominated to the Court, and these scores therefore cannot account for any ideological drift that occurs once a justice begins his/her tenure on the Court.

Another common measure of judicial ideology relies upon the votes of judges. Martin and Quinn (2002) updated Pritchett's methodology, using Markov Chain Monte Carlo methods to fit a dynamic item response model on the votes of justices. These Martin–Quinn Scores have become the most widely used measure of judicial ideology for scholars seeking to quantify the observed ideology of U.S. Supreme Court justices. Each justice receives a new score every term, allowing each justice's ideology to change over time, and providing a distinct advantage over measures, like the party of the appointing president, that remain static over a justice's entire tenure on the Court.

The measurement of judicial ideology is still an active research frontier. Traditionally, scholars have assumed that the

decisions of U.S. Supreme Court justices can be explained by knowing the judge's position on a single, liberal-conservative continuum. However, recent research has challenged this assumption. Lauderdale and Clark (2012) estimated a complex statistical model that allows justices' ideologies to vary by issue area, and they present persuasive evidence that the traditional one-dimensional view of judicial ideology is too simplistic, and that justices vary on their ideological location by area of law. Thus, for example, a justice could be fairly liberal on equal protection issues but conservative on criminal procedure cases. Determining the extent to which issue-level variation in ideology affects judicial decision-making is a major open question for scholars to investigate.

Other Justices

Strictly attitudinal explanations suggest that judges always vote sincerely; they only vote in ways that are congruent with their personal policy preferences. But these attitudinal explanations also pose a problem: empirical scholarship has demonstrated that justices sometimes vote strategically rather than sincerely. In other words, justices do not always vote in line with their personal preferences. As Epstein and Knight (1998) put it:

> Justices may be primarily seekers of legal policy, but they are not unconstrained actors who make decisions based only on their own ideological attitudes. Rather, justices are strategic actors who realize that their ability to achieve their goals depends on a consideration of the preferences of other actors, and the choices they expect others to make, and the institutional context in which they act (10).

Thus, under strategic explanations of judicial behavior, justices' beliefs about the consequences of their decisions are involved. Whereas strictly legal explanations posit single-minded judges, who are unconcerned about external reaction, and the attitudinal explanations expect judges to vote sincerely on every case without regard to sound public policy, the strategic explanations depend heavily on the expected interactions between and among actors within the political system.

Moreover, these strategic explanations of judicial behavior focus both on the legal rule adopted in the case rather than simply whether the case is decided in a liberal or conservative manner. In other words, this class of explanations acknowledges that judges can resolve a case in a 'liberal' manner in any number of ways: for example, they can issue a number of decisions or few decisions and they can rely on some precedents to the exclusion of others. Indeed, Maltzman et al. (2000) argue that the U.S. Supreme Court justices may occasionally vote against their personal preferences in order to achieve a final policy outcome that is more preferable to them.

Internally, this type of behavior is seen most clearly through the bargaining process that coincides with opinion writing. Epstein and Knight (1998) argue that individual justices often try to predict the votes of their colleagues in a case in order to act in a sophisticated manner. Therefore, an analysis that simply centers on the justices' votes may miss evidence of strategic behavior; analysis of judicial behavior under these strategic explanations must look beyond the vote on the merits and incorporate the construction of legal rules.

Strategic behavior happens throughout the process of writing opinions. Examining what they term 'the collegial game,' Maltzman et al. (2000) provides a variety of evidence that such sophisticated behavior happens on the Court. In particular, they show that justices are strategic throughout the entire process of drafting their opinions; decisions about how to respond to draft opinions and when to accommodate other justices' views are colored deeply by justices' strategic behavior.

If judges care about policy, then colleagues on their own court are not the only jurists whose actions they need to consider. While the Supreme Court lies at the apex of the federal judiciary, its decisions set precedent for the lower federal courts. Of course, lower federal judges are subject to the same life tenure as Supreme Court justices. Thus, it is difficult to force them to follow any particular Supreme Court precedent; they can theoretically ignore a decision of the Supreme Court without fear of retaliation. As a result, a variety of studies (e.g., Songer et al., 1994) have found that implementation of the decisions of Supreme Court by lower court is neither automatic nor apolitical. Thus, if justices are the policy-minded sophisticated actors posited by strategic explanations, one may expect to find that their voting decisions attempt to maximize the probability that lower federal courts will adopt and cite their legal policies. Murphy (1959) explored the relationship between the Supreme Court and lower federal courts, and argued that "[t]he Supreme Court must take into account the reaction of inferior judges" when making its decisions (1031). However, while many studies have investigated lower court compliance with Supreme Court precedent, there has been little research on the extent to which lower court behavior constrains the actions of the U.S. Supreme Court. Thus, while one may suspect that justices may adjust their voting to increase the probability of lower court implementation, there is no strong empirical evidence to support that assertion.

Courts and Legislatures

The U.S. Congress has the final say over the membership of the federal judiciary, and decides the Court's budget, the size of the federal judiciary, and even its jurisdiction. With Congress's broad powers with respect to the judiciary in mind, strategic explanations of judicial behavior suggest that Court may tailor its opinions in response to the preferences of other actors in an effort to increase the likelihood that the legislature will respond favorably to the decision (Epstein and Knight, 1998). Since other actors control the implementation of their decisions as well as their budget and salary, strategic explanations of judicial behavior suggest that external actors could constrain the Court through their control over various aspects of the judiciary.

Scholars have studied the relationship between congressional preferences and the Court's decision to hear a case. Of course, the Supreme Court has almost complete agenda-setting power; indeed, with few exceptions, the Court is able to choose between cases it would decide and cases it would decline to hear (Perry, 1991). With such wide discretion, there is reason to believe that the Court may act strategically to select certain cases and reject other, less desirable cases. Harvey and Friedman (2009) find evidence of a relationship between congressional preferences and the decision to hear a case in

their analysis of statutes passed between 1987 and 2000; using a statute-based data set and examining whether or not a particular statute is reviewed in a given year, they argue that the Court's docket consists primarily of cases in which the Court will face little constraint from the other branches of government as the justices reach their preferred ruling.

On the other hand, Owens (2010) uses data from the personal papers of the justices to compare attitudinal and strategic accounts of decision-making at this stage in the judicial process. Owens examines justices' votes to hear a case between 1953 and 1993, and his analysis considers alternate explanations about the agenda-setting process absent in Harvey and Friedman's study. Still, Owens finds no support for strategic behavior in any of his models. Given Owens's results and the weakness of Harvey and Friedman's findings, current research implies that any external constraint that does exist in the agenda-setting stage is weak, at best.

Political scientists have devoted substantially more attention to the content of the Court's final opinions and their relationship with the preferences of the other branches of government; again, the evidence is mixed. On the one hand, Segal (1997) and Sala and Spriggs (2004) found only negligible evidence of strategic voting behavior. In his study, Segal predicts justice's voting positions based on their preferences and then looks for evidence of strategic behavior as the political environment changes. Thus, Segal's approach allows him to compare directly attitudinal and strategic explanations; Segal finds that attitudinal explanations are superior in their ability to explain a justice's final voting behavior. Additionally, Segal and Spaeth (2002) update and refine Segal's work and reach a similar conclusion; they argue that justices' policy goals lead them to vote sincerely in the vast majority of cases. Furthermore, Spriggs and Hansford (2001), examining the factors that lead to the overruling of precedent by the Court, find no support for a separation of powers constraint; thus, there is strong evidence that the Court is not influenced by the ideology of the other branches of government.

Still, not all of the empirical evidence suggests that the Court is completely unconstrained by congressional preferences. First, Spiller and Gely's (1992) analysis of the Supreme Court's decisions in the National Labor Relations Board cases found that the Court was significantly constrained by congressional preferences. Second, Bergara et al. (2003) reanalyze Segal's data regarding congressional and judicial preferences using Spiller and Gely's methodology and find that justices act strategically in response to congressional and presidential preferences and that the level of constraint varies widely over time. Finally, Clark (2009) demonstrates that, over time, the Court's use of judicial review has been directly proportional to the number of court-curbing bills (such as legislation to reduce the Court's jurisdiction) recently considered by the U.S. Congress. As Congress becomes more hostile toward the Court, the Court becomes less likely to use its power of judicial review.

Courts and Executives

But what of the executive branch? The Supreme Court often invites the Solicitor General – the federal government's lawyer – to share his views with the Court in important cases, and his views are so important that he is often called the 'Tenth Justice.' The Solicitor General serves a number of important roles for the Supreme Court, including providing credible information about the case as well as a cue about the views of the executive branch. By providing additional legal argumentation as well as the official position of the executive branch on a given case, the Solicitor General plays a vital role in the Court's decision-making process.

Regardless of the specific role it serves, the Solicitor General is incredibly successful when he appears before the Court. Indeed, studies show that the Court is much more likely to heed the recommendations of the Solicitor General in either the merits or *cert* stages of its decision-making process than any other attorney or actor. Indeed, the Solicitor General is the winningest lawyer to consistently appear before the Court.

Organized Interests

Beyond mass public opinion, the justices may also heed the views of organized interests as they shape their docket and rule on the merits. The most common way for organized interests to participate in the decision-making process is by filing *amicus curiae* (friend of the court) briefs at the merits and/or *cert* stages of the Court's decision-making process. These *amicus* briefs provide the Court with additional legal arguments as well as cues about what sorts of groups support various positions in the case and how important the case is to the public.

Research suggests that the Court responds strongly to these briefs. Caldeira and Wright (1988) demonstrate that, as the number of *amicus* briefs filed at the *cert* stage increases (regardless of whether the briefs suggest the Court should hear the case), the Court becomes more likely to hear a case. Similarly, a wealth of other research suggests that the Court incorporates arguments made by interest groups in their *amicus* briefs into the final opinions, providing evidence that these briefs are an efficacious way for organized interests to shape judicial policy on issues they care about.

The Public

Beyond listening to the other branches of government, justices may also heed the will of the people. There are many reasons to expect that the Court is considerate of the public will as it decides cases. First, if the justices are strategic actors concerned about the implementation of their policies, they should pay attention to public opinion; Rosenberg (2008) notes that the Court's opinions only reach their full potential when they are in line with public opinion. Second, the Court may act strategically out of an attempt to increase its legitimacy. Since courts have neither the power of the purse nor the sword, maintaining institutional legitimacy is of utmost importance to Supreme Court justices (Gibson and Nelson, forthcoming).

While one typically does not think of the Court as a representative institution, Marshall (2008) argues that the Court's decisions have been consistent with public opinion in between three-fifths to two-thirds of cases since the 1930s. Furthermore, Marshall cites reasons to believe that the Court may pay attention to public opinion; for example, the Rehnquist court

referred to public opinion in about six of its opinions per year. If the Court references public opinion directly in the text of its decisions, then there exists a strong theoretical argument that the Court both is aware of and may be influenced by public opinion. In a study of state trial court judges, Nelson (2014) presents results that suggest that, as judges have access to better information about public opinion, they adjust their decisions to fall in line with citizen preferences.

However, evidence to support the claim that public opinion has a direct effect on the Court's voting behavior has been mixed. Epstein and Martin (2010) summarize the state of the literature in the title of their article: "Does Public Opinion Influence the Supreme Court? Possibly Yes (But We're Not Sure Why)." Their empirical examination finds, in line with other studies, that the Court tends to issue more liberal decisions as the U.S. public becomes more liberal and more conservative decisions as the public mood trends in that direction. Yet, there are two distinctive mechanisms through which this ideological change could occur. First, justices might simply respond to public opinion. In other words, public opinion has a causal effect on judicial decisions, and Supreme Court justices respond directly to public opinion. Second, justices are people, too. For that reason, the same social forces that lead the mass public to become more liberal (conservative) might also act on the justices, causing them to become more liberal (conservative). Thus, public opinion may only have an indirect effect on judicial decision-making. The two explanations are difficult to parse because they are often observationally equivalent.

Still, scholars have done their best to parse the two explanations. Casillas et al. (2011) develop a model that controls social factors that cause macro-level opinion change, allowing them to separate the effect of direct and indirect public opinion. Their results suggest that public opinion has a causal effect on judicial decision-making, particularly in nonsalient cases. Additionally, Uribe (2014) targets hypotheses to find specific evidence that justices directly follow public opinion to maintain high levels of public support. She finds no evidence that justices behave strategically in this way. Instead, her results suggest that justices vote based on their sincere ideological preferences and that the similarity between a justice's ideology and public mood affects whether justices vote in line with, irrespective of, or against public opinion.

Conclusion

The factors that affect judicial decisions are multifaceted and varied, and include legal, attitudinal, and strategic factors. Still, one must remember that each individual explanation is not mutually exclusive; understanding how judges decide cases is rarely simple as understanding the effect of a singular factor. Rather, judges' decisions result from a rich set of considerations that encompass both law and politics. Indeed, George and Epstein (1992) demonstrate that the predictive power of models that include just legal or just attitudinal factors is surpassed by a model that includes both of those factors. Likewise, the effects of one explanation may be condition on the effects of another. For example, Bartels (2009) shows that legal considerations condition the effects of ideology; the predictive power of ideology is enhanced in cases that grant judges broad discretion and is mitigated in cases where judges are constrained by law.

Additionally, one must remember that all of the explanations discussed here have focused upon average behavior on the U.S. Supreme Court. Surely, judges on different courts may be more or less affected by one of these factors than judges on a different court. For example, Zorn and Bowie (2010) show that the influence of ideology on judicial decision-making increases as one moves up the judicial hierarchy. Moreover, the effects of these explanations may vary across judges, even those who sit on the same court. Indeed, some judges may have different views of the judicial role that leads to individual-level variation in the predictive power of these explanations. This is an important frontier for future research.

Judicial Independence

Michael J Nelson, The Pennsylvania State University, University Park, PA, USA

Abstract

This article reviews the literature on the measurement and consequences of judicial independence worldwide. First, the article discusses the difficulties inherent in defining judicial independence. Next, the article describes various measures of *de facto* and *de jure* judicial independence and their properties. Finally, the article describes the consequences of judicial independence for politics and economic development worldwide.

Scholars have long been concerned about the ability of judges to make decisions without the fear of reprisal by external political actors. Because judges generally lack the legitimacy bestowed upon presidents and legislators by the electoral process, scholars have concerned themselves with the ability of judges to render legitimate decisions without undue external political influence. In other words, if judges are to fulfill a role as effective checks on the arbitrary and capricious use of power by the executive and legislative branches of government, they must be able to issue decisions that effectively limit the powers of those branches of government with the confidence that those decisions will be respected.

Given the normative importance of judicial independence, scholars have investigated both the determinants of judicial independence as well as its effects on the relationships between that judicial institutions and other actors within the political system and the effects of judicial independence on a variety of economic and political outcomes. Research indicates that the level of judicial independence enjoyed by a court affects both how judges make decisions as well as the economic prosperity of countries.

Still, while widely invoked in the literature, scholars have had widely divergent ideas about what it means for a court (or a judge) to be independent, as well as how one might know if a judge or court is actually independent. This article reviews the literature on judicial independence. It begins by defining judicial independence and exploring the two major facets of the concept – *de facto* judicial independence and *de jure* judicial independence – as well as the myriad ways scholars have attempted to measure both types of judicial independence. Next, the article discusses the effects of judicial independence worldwide with particular attention to the U.S. Supreme Court and the courts of last resort in the U.S. states. The article concludes with some comments about directions for future research on judicial independence worldwide.

Defining Judicial Independence

Scholars generally argue that an independent judiciary is an important feature of a country's political system because it enables the judiciary to serve as a strong check against arbitrary or excessive uses of power by the executive or legislative branches of government. However, scholars disagree about how one would know if a court is actually independent. As a result, any conceptualization of judicial independence must grapple with questions involving the types of protections to which judicial independence refers, from whom a court is independent, and the appropriate unit of analysis suggested by the notion of an independent court. These three questions highlight the difficulties inherent in conceptualizing judicial independence.

First, does judicial independence refer to formal protections from outside influence or more on-the-ground, practical considerations? This question is perhaps the major question that has vexed judicial scholars interrogating the concept of judicial independence. On the one hand, formal constitutional provisions provide a clear way to demarcate judiciaries with clear independent bases of power from those who do not have those protections. For example, we might believe that judges, like those who serve on the U.S. Supreme Court, who are granted life tenure at the time of their appointment are automatically more independent than those, like most in the U.S. States, who must rely on period reelection or retention in order to keep their seats on the bench. The logic is this: life tenured judges have no formal reason to mind the preferences of the legislature or the public in order to keep their position on the bench whereas judges who are subject to reelection or reappointment may be more likely to defer to the whims of the body who will eventually choose whether they should remain in office.

On the other hand, not all judicial powers are formally written in the constitution; indeed, the U.S. Supreme Court's power of judicial review appears nowhere in the text of that country's constitution. As a result, one might also measure judicial independence based on the extent to which a court is independent in practice, rather than according to formal institutional rules. Implementation provides a key example of the importance of considering judicial independence from a practical perspective. Even given life tenure, a judge must rely on some external actor, such as a bureaucracy or a legislature to translate her opinions into practice. To this end, even a judge who need not worry about her continued tenure on the bench may still, in practice, make deferential decisions out of a concern for implementation.

To this end, empirical scholars have tended to acknowledge that judicial independence can be partitioned into two categories: *de jure* and *de facto* judicial independence (Feld and Voigt, 2003). The former category assesses the separation of the judicial branch from the other branches of government

given the formal institutional rules and procedures that govern political actors; the concept of *de jure* judicial independence involves close attention to what Rios-Figueroa and Staton (2014) call "institutions of judicial insulation" (4). The latter category – *de facto* judicial independence – assesses the extent to which those rules and constraints actually function to affect the behavior of judicial actors. *De facto* judicial independence is present when a judge's (or court's) decisions represent her (or its) own preferences without regard for the preferences of other actors (Rios-Figueroa and Staton, 2014).

The second major question facing scholars concerns from whom a court is independent. Judges may be dependent upon many actors: bureaucrats who implement their decisions, lower court judges who interpret the decisions of high court judges, the public whose legitimacy courts need in order to make countermajoritarian decisions without reprisal, and/or the other institutions of government whose law and/or actions the Court must review. Any attempt to measure or discuss judicial independence requires scholars to determine both which of these individuals and institutions an independent court is liberated from and how to classify those courts who are independent from some of these actors but not other actors. Put differently, is a court only 'independent' if it can act free from the influence of the executive branch, the legislative branch, *and* the public, or might a court be independent if it is reliant on some of those actors but not others? To this end (and discussed in more detail below), scholarship addressing the measurement of judicial independence has tended to treat the concept as a continuum ranging from courts that are completely dependent on other political actors to, at the other extreme, courts whose actions are not reliant upon the will of those actors.

A final question facing scholars when defining judicial independence concerns the appropriate unit of analysis. In other words, is judicial independence a characteristic of countries, courts, or judges? Put differently, are judicial independence something that is constant across all courts within a country? Indeed, it seems increasingly likely (especially in countries or states where judges face highly political reappointment procedures) that a preference for judicial independence is best ascribed at the level of the individual judge. Such a theory is bolstered by findings, like those of Ramseyer and Rasmusen's (2001), that judges vary individually in their deference to other branches of government. Ramseyer and Rasmusen (2001) investigate the propensity of Japanese judges to rule against the government, and they find that career-minded Japanese judges are less likely to rule against the government in politically important cases for fear that ruling against the government will lead them to receiving undesirable career placements in the future. However, most traditional measures of judicial independence treat the concept as one which is a characteristic of a country.

Measuring Judicial Independence

Scholars have grappled with these three practical concerns discussed above when creating measures of judicial independence. Given the difficulties inherent in defining the concept, scholars have generated a variety of different ways to measure the extent to which a country's courts are independent. Given the distinction between *de facto* and *de jure* judicial independence, scholars have tended to develop measures of each concept separately. In this section, I review existing measures of judicial independence before discussing the empirical evidence about the relationship between *de jure* and *de facto* judicial independence. For a comprehensive discussion of each measure, see Rios-Figueroa and Staton (2014).

Measuring *De Jure* Judicial Independence

As discussed above, *de jure* judicial independence refers to the extent to which a court is formally freed from the influence of other political actors. Given that *de jure* independence is based upon formal, written considerations, scholars have relied heavily upon content analysis of constitutions when constructing measures of the concept. This section outlines the components underlying three prominent measures of *de jure* judicial independence.

Feld and Voigt's (2003) measure of *de jure* independence relies upon the presence of formal institutional characteristics of national judiciaries. The measure assesses the presence or absence of 23 characteristics in 12 categories, including constitutional amendment difficulty, judicial selection and removal procedures, salary protections, judicial review, and whether or not the highest court is required in the constitution. Feld and Voigt create an index that ranges from 0 to 12 and, due to a lack of data from some countries, divide the total number of indicators present within a country by the total number of indicators for which there is available data. The resulting measure is a continuous measure of *de jure* independence.

Keith (2002) dissolves the concept of *de jure* independence further into separate indicators of the concept; Keith's measure also relies upon content analysis of national constitutions. The resulting measure is composed of seven separate trichotomous measures, each corresponding to separate dimensions of *de jure* judicial independence. The scales include measures for financial autonomy, a separation of powers system, whether or not the constitution insures the finality of judicial decisions, and whether or not judges have exclusive authority over their jurisdiction.

A final measure of *de jure* judicial independence was derived by La Porta et al. (2004). Again relying on content analysis of national constitutions, La Porta et al. examine judicial tenure, judicial policy-making authority, and the extent of constitutional review to create a measure of "judicial checks and balances." La Porta et al. average each of these characteristics together and normalize the resulting score to create a continuous measure of judicial independence.

Since these three measures of judicial independence purport to measure the same concept, one natural question to ask is the extent to which the three measures suggest similar results for a given country. Rios-Figueroa and Staton (2014) conducted an analysis of the association between empirical indicators of *de facto* judicial independence and found disheartening results. Their results indicate that these different indicators tend to be correlated with each other at very low levels, suggesting that they are actually measuring different types of judicial independence. More importantly, the low correlation between the

separate indicators of *de facto* independence indicates that these measures are unstable measures of the underlying concept.

Measuring *De Facto* Judicial Independence

De facto judicial independence moves away from a reliance on formal guarantees of judicial independence toward more practical considerations regarding the extent to which courts appear to be independent in practice. To this end, measures of *de facto* judicial independence rely on data from two sources: expert judgments about the political climate in a given country and reports published by experts, such as the United States State Department. While the sources for the measures differ, each of the following measures attempts to quantify the degree to which the decisions of judicial actors are, in practice, constrained by the preferences of other political actors within their country.

Feld and Voigt's (2003) measure of *de facto* judicial independence draws upon a survey of experts and political elites. The measure includes length of tenure, the number of judges removed from office, judicial salaries, and compliance by other political actors in their implementation of judicial opinions. As with their measure of *de jure* judicial independence, the measure begins with a count of the number of characteristics present in a particular country, and Feld and Voigt divide that count by the total number of characteristics for which they were able to collect data for a particular country.

The Bertelsmann Transformation Index (2010) also relies on expert judgments to create another measure that captures *de jure* judicial independence. The scale ranges from 1 to 10, and it incorporates expert judgments on a number of factors including the extent of corruption, the presence of judicial review, the professionalization of the judiciary, and the institutional differentiation of the judiciary.

The Political Risk Services (2010) 'Law & Order' measure integrates both political and social attributes of the efficacy of the rule of law within a country. Both 'law' (based on "the strength and impartiality of the legal system") and 'order' (capturing the "popular observance of law") are measured on a separate, 0–3 ordinal scale, and the two scales are combined for the final measure (5). Thus, "a country can enjoy a high rating – 3 – in terms of its judicial system, but a low rating – 1 – if it suffers from a very high crime rate of if the law is routinely ignored without effective sanction (for example, widespread illegal strikes)" (5).

Yet another measure of *de facto* judicial independence comes in POLITY's measure of constraints on the executive (XCONST). The seven-point scale is used to score the relative level of restraint placed on the executive branch's ability to act. These constraints are based on the efficacy of' 'accountability groups' like "the ruling party in a one-party state; councils of nobles or powerful; advisors in monarchies [and] the military in coup-prone polities" in their attempts to constrain the executive (Marshall, 2010: 24). Along with these accountability groups, the independence of the judiciary is included as one factor that comprises this variable.

Henisz (2000) combines the POLITY measure with the Political Risk Services measure to form a dichotomous measure of judicial independence; in his measure, a country scoring at or above the median score on both scales is labeled independent while those below the median on one or both measures are labeled not independent.

Other measures of *de facto* judicial independence rely upon reports compiled by the U.S. State Department. In one such attempt, Howard and Carey (2004) code a judiciary as fully independent if it, in practice, functions independently of both the executive branch and the legislature, provides basic due process to criminal defendants, and is basically free of corruption and bribery. Their resulting measure is a three-category ordinal scale.

Other scholars have also relied upon the U.S. State Department's reports. Cingranelli and Richards (2008) construct a trichotomous measure of judicial independence using these reports; by their measure, a country has a fully independent judiciary if the court has the power of judicial review, judges on the national supreme court have a tenure of at least 7 years, court hearings are open to the public, judgeships are open to the public, political elites have limited removal power, and if actions of the political branches of the government may be challenged in the judiciary.

Tate and Keith (2009) construct a similar trichotomous measure using U.S. State Department reports. By their measure, a judiciary is independent if it operates with no mention of corruption or outside influence or interference from the executive or other branches of government.

Rios-Figueroa and Staton (2014) also analyze the extent to which various measures of *de facto* judicial independence seem to measure the same underlying concept. Their examination indicates that measures of *de facto* judicial independence tend to correlate with each other at higher levels than do measures of *de jure* judicial independence, providing some evidence of the reliability of these measures.

The Relationship between *De Facto* and *De Jure* Independence

Although scholars generally have developed separate measures of *de facto* and *de jure* judicial independence, a natural question to ask is the extent to which the two types of judicial independence are related to one another. To put the question differently, how well can we tell if a judiciary is independent in practice if we know how independent they are on paper? To answer this question, Rios-Figueroa and Staton (2014) conduct an empirical analysis of many of the measures discussed above. Their empirical analyses suggest that the two types of judicial independence are quite different from one another; measures of *de facto* and *de jure* judicial independence capture different underlying concepts. Moreover, given information about *de jure* or *de facto* judicial independence in one country does little to predict levels of the other type of judicial independence; measures of each concept are not highly correlated with each other.

The Effects of Judicial Independence

In addition to the major research programs attempting to quantify and conceptualize judicial independence, another

robust literature on the topic addresses the effects of judicial independence on politics and policy within a country and across countries. This section reviews the effects of judicial independence on countries worldwide, giving special attention to judicial independence at the state and federal levels in the United States.

Judicial Independence in Comparative Perspective

One major question regarding judicial independence concerns the cross-sectional effects of judicial independence on economic and political features of a country. Put differently, scholars have sought to determine the extent to which variations in countries' levels of judicial independence, both over time and across countries, affect government, politics, and economics in those countries.

One prominent concern in the literature relates to the relationship between judicial independence and a country's system of government. There is widespread evidence that judicial independence promotes democratic governance by lowering the stakes of being in power; by limiting the benefits leaders can capture by holding power, independent courts promote stable democratic governance (North et al., 2000). Likewise, Reenock et al. (2013) demonstrate that independent courts encourage the survival of democratic regimes, particularly in situations were compromise between classes is promoted by economic conditions.

Though high levels of judicial independence tend to promote democratic, rather than authoritarian, rule, some authoritarian countries do have independent judiciaries. Why do authoritarian governments permit independent courts? After all, authoritarian governments centralize power in the hands of a few people, and independent judiciaries are empowered to take action to limit the use of that power. Thus, it might seem irrational for dictators to allow independent courts to flourish. Moustafa (2007) investigates this question thoroughly, documenting the introduction of an independent judiciary in Egypt. His research demonstrates that authoritarian regimes allow independent judiciaries in an attempt to credibly commit to other countries that they will permit the rule of law, encouraging those countries to form economic linkages with their country.

Beyond studies seeking to explain the relationship between systems of government and levels of judicial independence, scholars have also sought to examine the relationship between levels of judicial independence and respect for rights. One set of studies has documented the importance of an independent judiciary for the protection of rights. North and Weingast (1989) argue that independent judiciaries are valuable because they make credible the promises of states to respect the rights of individual citizens. Empirical studies have tended to support this assertion, demonstrating that countries with greater levels of judicial independence tend to have higher levels of human rights protections (Keith, 2002; Powell and Staton, 2009).

Finally, another set of studies has documented the positive effects of judicial independence on a country's economic outcomes; by protecting property rights, independent courts are able to encourage economic development (North, 1990). For example, Barro (2000) documents the relationship between respect for the rule of law (*de facto* independence) and finds that economic growth is greater in countries with higher levels of respect for the rule of law, that investment is higher in countries with greater respect for the rule of law, and that countries with more respect for the rule of law have lower levels of income inequality.

Judicial Independence and the U.S. Supreme Court

The framers of the U.S. Constitution took a variety of measures to limit overt political influence on the decisions of the U.S. Supreme Court. The most obvious institutional shield against external influence on the decision making of the U.S. Supreme Court is the fact that all Justices are appointed for a period of 'good behavior' which, in practice, has come to mean life tenure. Justices who retire are still given a salary, a law clerk, and the opportunity to hear and decide cases. By eliminating the need to worry about either reappointment or a postjudicial career, the framers took strong steps to ensure the formal independence of the U.S. judiciary.

A variety of studies confirm the fact that, for the most part, there is little evidence that the overt preferences of other branches of government affect the decisions of the U.S. Supreme Court. In the most notable study, Segal (1997) finds no evidence that the U.S. Supreme Court is responsive to changing congressional preferences in its decision making. Likewise, Owens (2010) finds a similar effect as the Court selects its docket.

Still, other studies provide some evidence that the Court's *de facto* independence is not unshakable. Clark (2009), for example, documents an inverse relationship between the number of court-curbing bills (e.g., bills that attempt to limit the court's jurisdiction or to change the size of the court in an attempt to make it more amenable to the legislature's policy preferences) introduced in Congress in 1 year and the Court's propensity to use its power of judicial review to strike down a federal law in the following year. Likewise, the executive branch also plays an important role in the Court's work. The U.S. Supreme Court frequently asks for the formal opinion of the executive branches on the cases it is reviewing by inviting the Solicitor General to file an *amicus* (friend of the court) brief in a pending case or by inviting the Solicitor General to participate in oral argument. When the executive branch participates in a case, it is very successful; the Court is more likely to hear a given case after the executive branch has recommended review, and the Solicitor General is the winningest attorney that appears before the Court. Thus, there is some evidence that suggest limits to the Court's independence.

Judicial Independence and Judicial Elections

The literature on courts in the American states is replete with concerns about judicial independence. The American states are unique in that their judges, unlike every other judicial system in the world except the Bolivian national courts, are selected and retained through popular elections. The American states began to adopt judicial elections in the mid-1800s as a response to legislative overspending; judicial elections, the drafters of state constitutions believed, would reduce legislative deference to the legislative branch, empower courts to use the power of

judicial review to curb legislative overspending, and increase levels of judicial independence (Shugerman, 2012). Similar arguments were made in Bolivia with the ratification of their 2009 constitution; judicial elections were initially adopted in both circumstances as a way to empower courts and increase judicial independence from the traditionally elected branches of government.

In the United States today, though, judicial elections are seen as a mechanism to promote judicial accountability (Nelson, 2011). Because one major function of popular elections in a democratic political system is to promote accountability by encouraging elected officials to heed public will and suggesting that voters should incorporate retrospective evaluations of candidate performance as one element of their voting calculus, opponents of judicial elections argue that these institutions weaken the independence of the judiciary by making judges over-reliant on public opinion. Supporters of judicial elections would counter that argument with one made by some of the leading researchers on the subject: "at the state level, law should represent public preferences and political culture, as long as the mandates of the United States Constitution and other federal law is [sic] observed" (Bonneau and Hall, 2009: 15).

The empirical literature on the effects of judicial elections on the independence of the judiciary suggests that all judges – regardless of how they are selected and retained – respond to some sort of external influence, but the method that is used to select and retain a judge changes the external influences to which a judge responds. Scholars have determined that judges who are popularly elected tend to follow public opinion more closely in their decisions on high-profile issues (such as the death penalty) than judges who will never stand for election (Brace and Boyea, 2008). Additionally, research suggests that the type of election that is used conditions the extent to which judges are congruent with public opinion in their decision making. For example, judges who run in elections that do not provide information on their party affiliation to voters on the ballot tend to follow public opinion more closely than judges who run in partisan elections (Caldarone et al., 2009). Still, the literature provides little reason to believe that appointment systems are a panacea for judicial independence. Indeed, Johnson (2014) shows that judges who never face election, but are appointed by governors or legislators, are less likely to rule against executive power when given the chance. Thus, it seems that judicial selection is less a question about judicial independence from all external influences but rather a question about from which influences one wishes judges to be independent.

Conclusion

Judicial independence is an important concept in an array of work on comparative and domestic judicial politics, and scholars have developed a number of different measures of the concept. Yet, while each measure purports to measure one part of the same concept, there are significant empirical and theoretical limitations among the measures; some measures capture concepts other than judicial independence, many of the measures make strong assumptions about the nature of judicial independence, and many measures of seemingly the same concept are correlated with each other at very low levels. Thus, future research should continue to unpack the concept of judicial independence at a theoretical level and work to create new, theoretically grounded, measures of the concept.

Future work on judicial independence will continue the work of Rios-Figueroa and Staton (2014) to determine the extent to which empirical indicators of judicial independence actually capture the concept they purport to measure and to examine the relationships between various empirical indicators of judicial independence. Rios-Figueroa and Staton's findings that measures of *de facto* and *de jure* judicial independence are quite different from one another should give scholars pause about conflating the two concepts. Future work on the topic should examine the conditions under which *de facto* and *de jure* judicial independence are closely related within a country and the conditions under which they are not.

Judicial Review

Jesse Merriam and Joel B Grossman, Johns Hopkins University, Baltimore, MD, USA

© 2015 Elsevier Ltd. All rights reserved.

This article is a revision of the previous edition article by J.B. Grossman, volume 12, pp. 8020–8024, © 2001, Elsevier Ltd.

Abstract

Judicial review may be defined as the institutional capacity and authority of courts of law to assess the validity of actions taken by both lower courts and coordinate branches of government. The following article traces the doctrine's historical origins, examines its sometimes tense relationship with theories of democratic governance, explores its recent globalization beyond the United States, and concludes with discussion of contemporary debates concerning the judicialization of politics.

Judicial review may be defined as the institutional capacity and authority of courts of law to assess the validity of actions taken by both lower courts and coordinate branches of government. In the United States, judicial review has been associated historically with Supreme Court decisions regarding the allocation of powers among the branches of the national government, and between the national and state governments. In the last half of the twentieth century, the federal judiciary also used the power of judicial review to play a prominent role in protecting individual rights. Most modern nation-states now incorporate some variant of this power into their laws and constitutions.

Historical Origins

Judicial review is an outgrowth of efforts to limit the scope of power held by those authorized to interpret both sacred and secular texts. Societies, particularly (but not exclusively) those with complex governing structures, have created systems of law that constrain or influence official and social behavior through expressed codes or instructions. These, in turn, are overseen by special, trained officials. The fear that written laws and those empowered to enforce them will subvert the basic structures and values of a society form a prominent chapter in the history of self-government. Enabling government while protecting against its abuses is both an age-old and universal concern.

In the Judeo-Christian tradition, for example, one finds such concerns in the books of Exodus, Leviticus, and Kings I and II. There, following the example of the primary lawgiver, Moses, the prophets often contested the interpretations of both sacred and civil law provided by the kings and other secular rulers. Likewise, intellectuals in ancient China engaged in an extensive debate over whether *li* (ritual) or *fa* (law) should govern human behavior. Mo Tsu, one such intellectual, argued that government is necessary to establish and govern meanings, including those pertaining to human conduct. Other ancient Chinese intellectuals countered that the attempt to codify essential rituals or forms of conduct would lead to sophistry in political life. The prince's advisors, it was reasoned, would confuse the prince with various interpretations of essential political terms (Pocock, 1971).

Tension with Democracy

In modern democratic polities, the dilemma presented by judicial review is often referred to as the 'countermajoritarian difficulty' (a phrase famously coined by Alexander Bickel). This term recognizes the tension between democracy and the rule of law. In many legal systems, judges are not elected through the political process, but are rather appointed by elected officials (often for life), thereby giving the judiciary some, though by no means an absolute, independence from political influences. Because courts are thus somewhat insulated from political pressures, many commentators have seen judges as ideal guardians for protecting minorities from the tyranny of the majority and for preserving a political system's fundamental principles and values. On this ground, British jurist A.V. Dicey famously contended that an impartial and independent judiciary is central to the rule of law. Yet because courts are often not majoritarian democratic institutions, their decisions and interpretations of laws and constitutions may be at variance with popular values. There is always the fear that, in the guise of interpretation, a judge will substitute his or her personal values for those of a democratic majority or the preferences of a previous ruling party.

The emergence and practice of judicial review in the United States provide a textbook example of this continuing tension between democracy and the rule of law. Although the US Constitution does not explicitly mention judicial review, the founders were quite familiar with the practice. The doctrine had precedents in English law, the most famous of which is *Bonham v. College of Physicians* (1610), also known simply as *Dr Bonham's Case*. That case arose after the Royal College of Physicians sought to punish Dr Thomas Bonham for practicing medicine without a license issued by the college. The Court of Common Pleas ruled that even though an Act of Parliament had authorized the college to act in this way, Dr Bonham still could prevail in his suit challenging the legality of the punishment, because, in the words of the court's chief justice, Sir Edward Coke, "when an Act of Parliament is against common right and reason, or repugnant, or impossible to be performed, the common law will control it, and adjudge such an Act to be void."

Drawing from this principle, the US Supreme Court held almost 200 years later in *Marbury v. Madison* (1803) that "it was the province and duty of the judicial department to say what the

law is," and that, under a written constitution of enumerated powers, the Court could not enforce a law repugnant to it. The facts of the *Marbury* case, springing from the acrimonious 1800 presidential election and the resulting showdown between the outgoing Federalists and the incoming Democrat-Republicans, underscore the political dimensions of judicial review.

After Thomas Jefferson defeated John Adams in the 1800 election, Adams spent his last days in office seeking to fill as many governmental positions as possible with Federalists. To this end, Congress created and Adams appointed many justices of the peace in Washington, DC. But before the last of these commissions could be delivered, Jefferson's tenure as president began, and Jefferson promptly ordered his secretary of state, James Madison, not to deliver any of the remaining commissions. William Marbury, one of the appointees yet to receive his commission, brought a suit in the Federalist-dominated US Supreme Court to order Madison to deliver the papers. Chief Justice John Marshall, a leading Federalist whom Adams had appointed to the Court in his final months as president, began the Court's opinion by noting that Marbury was indeed entitled to his commission. Nevertheless, Marshall continued, the Court did not have the authority to mandate its delivery, because the Constitution did not give the Court original jurisdiction over the matter. Therefore, Marshall concluded, the federal statute that authorized Marbury to bring the suit to the Supreme Court was invalid.

Before the *Marbury* decision, state courts had exercised this power of judicial review, but until that point no court had declared the power so forcefully as Marshall did; he held that the US Constitution is supreme over ordinary statutes and, moreover, that the Constitution specifically makes the judiciary the ultimate arbiter of its meaning. The *Marbury* decision thereby carved the path for the federal judiciary to invalidate any governmental action inconsistent with its understanding of the Constitution. In locating this judicial power in the US Constitution, Marshall pointed to many sources, such as the general structure of the document, specific provisions dealing with the judiciary's duty to uphold the Constitution as the supreme law of the land, and Alexander Hamilton's claim in Federalist 78 that the judiciary must be able to use its power of persuasion to counter the executive's sword and the legislature's purse.

Many scholars have challenged Marshall's reasoning as vastly oversimplifying whether the Constitution does indeed contemplate a power of judicial review, let alone an exclusive power setting the court as the ultimate arbiter of the Constitution's meaning. But almost all scholars recognize the political acumen that Marshall displayed, refusing to enlarge the Federalists' power in that particular instance while at the same time significantly broadening the Supreme Court's power overall to invalidate legislative enactments it deems unlawful. By not mandating the commission, Marshall made it appear as though he was exercising judicial restraint and not furthering the Federalists' agenda. But in so doing, he expanded the authority of the only branch of the federal government, the judiciary, still dominated by Federalists. Jefferson saw through Marshall's plan, writing that judicial review was "a very dangerous doctrine indeed," but he had little choice but to accept the ruling, being that it gave him what he had wanted, the denial of Marbury's commission.

Given this danger of the judiciary invalidating an action taken by a coordinate branch of government, there is always the possibility that the other branches will use their powers over the sword and purse to ignore a judicial decision, and for this reason the Supreme Court has often exercised great caution in exercising judicial review. Indeed, the Court invoked the power sparingly in the nineteenth century, invalidating only a few laws as unconstitutional during that time. But in the twentieth century, as the doctrine gained acceptance among the citizenry, the scope and incidence of judicial review expanded rapidly. Today, it is a centerpiece of a 'judicialized' American political system. Nevertheless, although there is general agreement at the theoretical level about the utility of judicial review, there is still disagreement about its application in particular cases and the alleged perils of an 'imperial judiciary.' Indeed, a handful of scholars, most notably Alexander Bickel, Sandy Levinson, Mark Tushnet, and Larry Kramer, have contended that the nation would be better served by eliminating or at least vastly narrowing the power of judicial review, because, according to these thinkers, judicial review undermines the democratic process and this harm outweighs any benefits that might accrue from the doctrine (Bickel, 1986; Levinson, 1989; Tushnet, 2000; Kramer, 2004). One could say, then, that the battle between Marshall and Jefferson continues into the twenty-first century.

Globalization of Judicial Review

As Americans continue to debate the use and consequences of judicial review, it has taken root elsewhere. Many postwar constitutions in Europe, as well as India, South Africa, and Japan, incorporated some variant of it. And it now has been adopted, at least formally, by many of the nations of the former Soviet empire. Many of these nations had, in fact, once deliberately rejected it. Post-Napoleonic Europe, for example, firmly placed the judiciary under the control of the positivistic codes and enactments of the parliaments. And many of the Asian countries struggled throughout the nineteenth and early twentieth centuries to develop independent judiciaries that would be 'acceptable' to the United States and the other Western powers (Grovogui, 1996; Millard, 1931). The rise of authoritarian and totalitarian regimes with little regard for basic human rights in the twentieth century led to an 'Americanization' of the governing regimes in Turkey, the Philippines, Japan, France, and Germany after World War II. All of these nations have joined many others in adopting some measure of constitutional and liberal reform in their political arrangements, reforms that include an expressed power of judicial review. In Africa, judicial review and 'constitutional courts' have taken root in places like Benin, South Africa, Ghana, and many other countries where, previously, the judiciary was almost completely subservient to the executive or legislature (Shapiro and Stone, 1994; Prempeh, 1999).

In the United Kingdom, which has no written constitution, no bill of rights, a strong tradition of parliamentary supremacy, and no formal mechanism for judicial review, in the same period that the United States was undergoing a transition toward a more 'activist' judiciary with respect to civil rights, British judges increasingly policed the administrative realm for violations of governing statutes. Some scholars have looked to

internal factors, such as intergovernmental support and rights advocacy organizations, as well as the influence of the increasingly rights-oriented and litigious culture of the United States, to explain the development and persistence of what might be called clandestine review (Shapiro and Stone, 1994; Epp, 1998).

Nevertheless, courts in Europe, Africa, and Asia have retained much of their traditional character and have not adopted a full-fledged version of American judicial review. This is particularly true of countries with civil code rather than common law systems. Most European constitutional courts, for example, are special 'constitutional' courts that hear cases principally brought by the government, although this is not the case for all European nations; Germany, for example, has a special procedure to hear lawsuits brought by private litigants. In France, a civil code country, the Constitutional Council may review legislation only in the immediate time period after passage and prior to promulgation. Moreover, the fact that members of both the Assembly and Senate can, with great ease, bring a constitutional challenge to legislation has further blended the edges separating legislating from adjudicating. The legislator proposes and debates a law 'as if' a judge will hear the same; and judges write decisions 'as if' the audience will be a legislator. Whether the parliament is the creature of the judge or the judge is the creature of the parliament is in all respects an important question (Shapiro and Stone, 1994: pp. 400–402).

Characteristics such as those retained by the French point to important departures from American cultural and jurisprudential conventions. The US Supreme Court has never viewed itself as a court of 'instruction.' Indeed, the Court has consistently held that it lacks the power to issue merely advisory opinions; pursuant to Article III of the US Constitution, federal courts may adjudicate cases only in the context of an adversarial 'case or controversy' proceeding. Organizing principles of government such as federalism and the separation of powers also vary widely in their acceptance, meaning, and application, thereby insuring many variants of judicial review. Recent research shows that over the past decade, foreign courts have been citing American courts less and less frequently, and many nations have been moving away from the American structure of governance. Some scholars attribute both phenomena to the United States' declining influence and status as a hegemonic power. If the United States' power abroad further declines, as many predict it will, the variations of judicial review will likely increase, making the massive power employed by the US Supreme Court through judicial review even more of an anomaly.

Judicialization of Politics?

Although few nations have adopted the robust form of judicial review currently practiced by courts in the United States, it is clear that judicial review has become a global phenomenon, leading some social scientists to speak of a 'judicialization' or 'juridicalization' of politics. At its root, the thesis suggests that political institutions such as legislatures and administrative agencies have come to expect and even welcome courts as arbiters or overseers of their actions. They tailor their actions to accord with an expected response by the judiciary (Stone Sweet, 1999: p. 164; Shapiro, 1994). The electorate itself has come to have similar expectations. In the American political context, for example, judicialization has had the paradoxical effect of legitimizing, *de facto*, the role of judicial review in a democratic process. While most Americans lack a deep knowledge of American history, politics, or law, the judicialization of politics has enabled them to speak the language of rights. Many Americans can, with some measure of accuracy, defend or dispute the validity of the legal holdings involved in such famous cases as *Brown v. Board of Education* (1954), *Miranda v. Arizona* (1966), and *Roe v. Wade* (1973) (Friedman, 1990; Grossman and Epp, 1991). The judicialization of politics has also led many Americans to believe that the US Supreme Court is and should be the final arbiter of legal disputes and that this does not contravene any basic democratic values, despite the fact that federal judges are not elected. Judges, in this view, are the lesser of many evils in a world where state and national institutions have come to be mistrusted. What citizens oppose most are decisions with which they disagree!

Outside of the United States, the tension between judicial review and democracy has been even less of an issue in the public eye. This is due, without doubt, to the association of judicial review with postauthoritarian reforms and constitutions that establish the primacy of fundamental human rights principles and entrust their protection to constitutional courts. The rise of supranational courts, such as the European Court of Justice, has not only created a second level of review that transcends the courts and laws of individual countries, but also added considerable force to the argument that the enforceability of basic rights is critical to the maintenance of democracy and a civilized world order.

The legal philosopher H.L.A. Hart pointed out years ago that judicial review, or some variant of it, is going to be a problem to any political community in which those who are authorized to make or interpret the laws governing the community are institutionally distinct from the community at large. In such cases, the conflict of law is often a matter of making both first-order laws, such as constitutions, electoral systems, and branches of government, and secondary laws that guide and constrain rule making (Hart, 1961). In less theoretical terms, the nature of the legal system becomes itself part of the political vocabulary of the system. This, after all, is what the 'judicialization' of politics is about: political actors adopting legal and constitutional discourse to express their political views. Governing structures and particular social and political conflicts are continually readjusted to each other as officials and some segment of the public alike discuss what is taking place and whether it conforms to basic political and legal arrangements.

Contemporary Debate

While the American literature on judicial review might seem to be of immediate and obvious interest to legal reformers in Europe, Asia, and Africa, it remains to be seen whether the American experience (or the 'countermajoritarian difficulty,' for that matter) will be of deep interest in those places. Rather, as judicial review has become less a species of American exceptionalism and more of a global practice, current scholarship has turned increasingly to a hybrid of the American debate. At issue is

the empirical question of *why* judicial review develops in some times and places and whether, normatively speaking, judicial review may be better employed in some systems than in others.

Some scholars have argued that for judicial review to take root, there must be some level of commitment to the rule of law, and to government that is both democratic and limited. In polities where pure majoritarianism prevails, there is, of course, no necessary limit to what the legislature can do in the electorate's name. Where the government is limited by some overarching set of principles, the ability of courts of law to intervene and veto legislation in apparent conflict with such principles is more pronounced (Shapiro, 1998). In a twist on the American experience, then, the inversion of the relationship of rights-to-the-state in regimes throughout Europe after World War II has enshrined their constitutional courts as defenders of preexisting and constitutive rights held by the citizenry. Many of these rights find their sources not merely in written constitutions (such as in the German Basic Law's protections of 'human dignity') but also in sources both internal and external to the political system (e.g., treaties and conventions) (Shapiro and Stone, 1994). Conversely, in some African countries like Ghana, the long-standing tradition of judicial deference to executive authority has led judges to use their new powers to adopt a jurisprudence seemingly at odds with the more recent, liberal written constitutions. In these nations, commentators have suggested, new 'constitutional courts' with judges learned in foreign jurisprudence and committed to constitutional reform will have to be substituted for a judiciary that is, in large part, a holdover from the *ancien régime* (Prempeh, 1999).

Other oft-cited factors influencing the development of judicial review include the existence of commerce and internal geographic and cultural divisions, such as federalism. Commercial actors conventionally use legal devices to secure both formal agreements and sanctions should the terms of those agreements be violated. Written law and the search for a neutral third party who is an expert in such law have long been important parts of trade. Social scientists have argued that commerce was of great importance in accounting for the historical emergence of judge-made law. The origins of the professional lawyer, Max Weber argued, are to be found in the *cavere*, the Roman practice of drafting contracts, wills, and other legal devices. The lawyers, seeking to make commercial relations more predictable for their clients, would change the meanings of extant legal terms or invent new legal devices and then seek out judges who would institutionalize the changes as authoritative (Weber, 1954: p. 72).

The existence of federative or federal government is also cited as a factor in how judicial review develops in a given country. Horizontal divisions of power among disparate electoral, legislative, and executive bodies, as well as vertical divisions of power, invariably occasion conflict that is itself caused by, and therefore cannot be corrected easily by, 'normal' political procedures. In countries experiencing such conflict, the judge might be seen as the best means of clarifying or mediating the existing division of power among these governmental entities, with the judge taking on the role of a theorist of the state and its basic arrangements (Dworkin, 1986).

Supranational courts, such as the European Court of Justice, have added yet another layer of review. That Court, for example, has claimed a sweeping power of judicial review for itself by converting the various treaties it oversees into a sort of overarching constitution binding on both member nations and the courts and citizens of those nations. Such a practice undermines the close connection between judicial review and national sovereignty, and it may also contravene basic principles of international law, at least in theory. Yet the European Court has been successful in part because it provides stability and some manner of coherence, while also balancing national sovereignty interests with the goal of nation-state integration.

Scholars also cite more temporally specific factors as relevant to the development of judicial review. In the United States, commercial elites have dominated constitutional litigation for most of US history. But this changed substantially in the postwar era, when nontraditional litigants were able to pool time, monetary resources, and available legal talent to press for important constitutional guarantees (Epp, 1998). And the US Supreme Court, over time, 'adjusted' the Constitution to facilitate the development and legitimacy of the American welfare state. In Europe, somewhat differently, the devolution of legislative power in parliamentary systems and the concomitant rise in cabinet- and party-enforced government have occasioned a role for courts, particularly in those countries (e.g., Germany) where even a governing majority cannot prevent legislation from being referred to the constitutional court (Shapiro and Stone, 1994: p. 405).

French social-historian and philosopher Michel Foucault argued that, since the early modern period, juridical institutions and discourses have been displaced gradually by administrative institutions and their discourses. The world of sovereigns and their landed jurisdictions had given way to a world of populations and institutions to 'normalize' these populations (Foucault, 1978). If we take both the American experience and the recent proliferation of legal and constitutional norms in Europe and elsewhere as our guide, the thesis would have to be revised to account for the appearance of administrators who come garbed as judges. The influence of legal and constitutional norms, vocabularies, and institutions on the socioeconomic and political structure of much of the planet has been considerable; the effects of this process are, however, to date poorly understood and in need of further study. In this respect, 'postmodern' arguments have to be seriously qualified. Whether justified in fact and theory, the expectation that judges and legal norms can ground individual rights and provide a constitution for transnational and intercultural contact is shared increasingly today. The very American *Marbury*, as it were, has found a place for itself in the global environment.

Jung, Carl Gustav (1875–1961)

Angela Graf-Nold, Zurich, Switzerland

Abstract

Carl Gustav Jung (1875–1961) was one of the main founders of psychoanalysis and general depth psychology, beneath Sigmund Freud and Alfred Adler. He was copy editor of the first academic psychoanalytic periodical *Jahrbuch für psychopathologische und psychoanalytische Forschungen* (ed. by Bleuler and Freud) and founder and president of the International Psychoanalytic Association (1910–13). With an academic background from the Zurich school of psychiatry (Burghölzli clinic, University of Zurich), encounters with Freud, and in confrontation with his own unconscious processes, Jung developed his own psychological approach under the term *analytical psychology*. His research was centered around the nature and the typical constellations of the psychic functions (reasoning, feeling, sensation, intuition) and their relations to the individuation process, as well as the nature of the unconscious and its relation to consciousness (archetypes, cross-cultural patterns of the individuation process, synchronicity).

Jung was born in Switzerland at Kesswil, near Lake Constance, on 26 July 1875, son of the parson Paul Jung and his wife, Emilie B. Preiswerk; in 1902 he married Emma Rauschenbach (1882–1956), daughter of a wealthy manufacturer, with whom he had five children, one son and four daughters. He died at the age of 85 on 6 June 1961, in his house in Küsnacht, Lake Zürich.

In 1895, Jung began his medical studies at the University of Basel. The sudden death of his father in 1886 caused some financial troubles, and left him to take care of his mother and sister Gertrud, who was 9 years younger than he was. His poverty contrasted with the continued reputation of both of his late, well-known grandfathers, both fathers of 13 children and both professors at Basel University. Carl Gustav Jung, Senior (1794–1864), a political refugee from Mannheim, Germany, had been a professor of medicine and president of Basel University. Samuel Preiswerk (1799–1871), C.G. Jung's maternal grandfather, professor of theology and ancient Hebrew at the university, had served as the president of the reformed ministers in the Basel Canton.

After his exams in December 1900, Jung decided to leave Basel and follow a professional career as a psychiatrist, beginning as a second assistant at the psychiatric hospital Burghölzli in Zurich. At the time, the Burghölzli asylum, southwest of the city of Zurich, was under the direction of Eugen Bleuler; it was then the most 'modern' institution for mentally ill persons, was affiliated with the University of Zurich, and its director was at the same time also professor of psychiatry at the university.

The context of the work at Burghölzli asylum is visible in Jung's later work. The reputation of Burghölzli asylum was the merit of Bleuler's predecessor Auguste Forel, who during his 20 years directorship from 1879 to 1898 had established the professional standards of the daily routine in the clinic and had set legal standards for admission, treatment, and dismissal of the patients; with regard to the discipline of psychiatry, he outlined and represented an unbiased empirical approach to mental phenomena, focusing as well on the neurological, psychological, and social aspects of mental disorders (bio-psycho-social model of mental illness/Zurich school of psychiatry). At the beginning an ardent pioneer in neurology, the everyday misery of his patients soon led him to abandon neurological research; instead, Forel (a Swiss francophone) introduced hypnosis (as practiced by the 'French School of Nancy' of H. Bernheim) as a first psychotherapeutic treatment for inpatients. In hypnosis, Forel found the proof for the existence of subconscious processes that were equivalent to externally observable neurological phenomena (scientific monism). His textbook on hypnotism became very famous and is still available in print (Forel). In 1898, Forel quit his job in order to dedicate himself further to the prevention of mental illness; he wrote an international bestseller about sexual education, *The Sexual Question*, 1905, and internationally got involved in promoting alcohol abstinence. Still very active as an organizer, author, lecturer, and psychiatric expert, he stayed a dominant figure in Swiss psychiatry, and was a critical observer of the activities at the Burghölzli clinic where Jung soon began to play a dominant role.

Bleuler, who was director of the clinic when Jung started, wholeheartedly shared Forel's conception of mental illness. As Forel's assistant, he had supported him in his pioneering neurological research, then he had participated very actively in the exciting introduction of hypnosis at the Burghölzli 1885/86. In 1886, he took over the directorship of the remote asylum Rheinau, an institution for about 400 chronically, mentally ill patients; there he lived as a bachelor with only one medical colleague and the housekeeper's family together with the patients.

As director of the Burghölzli clinic, Bleuler obviously appreciated the end results of his scientific and personal isolation. He immediately established a scientific debating club for his medical staff and other colleagues, which met weekly, alternating in the Burghölzli and in the private clinic of his colleague, the Russian–Swiss neurologist C. von Monakow. This circle constituted an important part of the 'creative scientific community' (Loewenberg, 1995) of the Burghölzli staff; the debates about Freud and psychoanalysis began here, and finally psychoanalytic interpretations were applied not only to patients' behavior and dreams but also mutually to colleagues and friends.

It was this environment that Jung experienced at Burghölzli hospital; it was quite a shock and like an entrance in a "monastery of the world." Four medical doctors, beneath Bleuler, as well as a secondary doctor and one ordinary assistant, were in charge for about 400 mentally ill patients; he and his colleagues lived as interns in single rooms; the director and the secondary doctor had apartments, and about 80 waiters slept on foldaway beds in the patients' rooms or in the corridors and could go home only once every two weeks.

"My inability to understand gave me such a sense of inferiority, that I couldn't bear to go outside the hospital" (Jung, 1925/1989). He read through the available literature and dedicated himself to the study of his cases. Soon he began his dissertation, 'On the psychology and pathology of so-called occult phenomena.'

1902

In this doctoral thesis, Jung studied his spiritualistic experiments with his cousin Hélène Preiswerk, which he had carried out with her at the end of his medical studies, and treated her case in the context of (hysterical) patients of the Burghölzli hospital. In a quite minor context, he referred to Freud and Breuer's *Studies on Hysteria* and to Freud's *Interpretation of Dreams*, but mainly he relied on the new studies of Pierre Janet and Théodore Flournoy. Flournoy, professor of psychology in Geneva, had just published a scientific best-seller *Les Indes à la Planète Mars* (1900), a long-term study of a spiritualistic medium. Jung got in touch with Flournoy and showed special appreciation for his 'objective-distanced' approach to mental phenomena (which was influenced by his personal friend William James) and his having arranged the new findings in a bigger context. Jung's untroubled friendship with Flournoy outlasted the much more famous, but never as untroubled, friendship with Freud, which began several years later.

In October 1902, Jung quit his strenuous job at Burghölzli. He went to Paris to study at the Collège de France with Pierre Janet and also learned English at the Berlitz School. In 1903, he married 21-year-old Emma Rauschenbach, the daughter of a factory owner, and settled in Zurich. At the end of 1903, he returned to Burghölzli hospital, initially as an external representative for the resident doctor who had fallen ill. In December 1904, he finally took over the regular post of resident doctor, and moved into the doctor's family apartment at the hospital. Three of his five children were born there and grew up together with Bleuler's family. Bleuler had also recently married the philologist and writer Hedwig Waser, one of the first academic women in Switzerland. Both women shared the interests of their husbands and took part in their scientific discussions; doubtless, there also existed a common role expectation for both wives to support their husbands in their professional duties.

This 'participation of everybody' was due to Bleuler's ideal of an 'active community' (*tätige Gemeinschaft*). Bleuler's previous experience as director of the remote Rheinau asylum, with the close contact with mostly 'incurable' chronically mentally ill patients, had led him to emphasize the obvious therapeutic value of an 'active community,' in which everybody worked according to their abilities in meaningful activities. For his special scientific research interest in this field – the dynamics of psychotic behavior – he favored a hypothesis of neurological conditions that caused a specific discontinuity in the forms of association.

Therefore, it was with some enthusiasm that, in 1904, Jung and Bleuler set up a well-equipped psychological laboratory for association experiments. These played a prominent part in psychological research at the time, especially in the school of Wilhelm Wundt at the University of Leipzig (Germany). Their findings soon led to passionate debates in the debating club. In giving accounts not only of the regularities of the test persons' responses to the stimulus words, as was usual in the Wundtian approach, but also to the 'intruders in the mind,' the irregularities (delays of reaction times, repetitions, and other disturbances), Jung and his coworkers (initially Franz Riklin, Sr., Jung's wife, Ludwig Binswanger, and several volunteers) identified the 'emotional-toned complexes' (*gefühlsbetonte Komplexe*) of the test persons as autonomous expressions of their repressed or dissociated unconscious conflicts. These results were particularly decisive for Jung. Behind completely 'mad' behavior he discovered quite normal hopes and desires. Paranoiac ideas and hallucinations revealed their hidden sense in the context of the patient's life stories. "At the bottom we discover nothing new and unknown in the mentally ill; rather, we encounter the substratum of our own nature," he stated. "That was at that time a very moving experience" (Jung and Jaffé, 1963).

When Jung was preparing a paper for his application as lecturer at Zurich University in 1905, he realized that his findings threw a new light on Freud's theory of repression. He decided to stand up for him, despite Freud's bad reputation in academic psychiatry. In 1906, Jung published a first volume of Association Studies, which he sent to Freud in Vienna. In 1907, he published *On the Psychology of Dementia Praecox*, which included a detailed case study with association experiments of an old female patient of the clinic, who since Forel's time had served as a demonstration case for students. These two publications inaugurated a remarkably passionate personal relationship with Freud, which is documented in hundreds of letters (Freud and Jung, 1974). Bleuler shared a special enthusiasm for Freud, although, like Jung, he was always somewhat critical about Freud's recently elaborated sexual theory and especially criticized Freud's dogmatic, sectarian tendencies as an impropriety toward the scientific community (Freud and Bleuler, 2013). In October 1907, Jung – against some opposition from Bleuler's side – founded an informal 'Freud Club' at the Burghölzli, which met independently from the other regular scientific staff meetings. In April 1908, Jung organized a first Psychoanalytical Congress (private meeting) in Salzburg. On this occasion, a first joint publication was founded – the *Jahrbuchfür psychopathologische und psychoanalytische Forschungen*, edited by Bleuler and Freud, and compiled by C.G. Jung. Thus Jung, with the decisive support of Bleuler, inaugurated the reception of Freudian psychoanalysis in academic psychiatry and the beginning of the so-called 'psychoanalytic movement.'

The culmination of – as well as the turning point in – the relationship of Freud and Jung was their joint trip in September 1909 to the 20th Anniversary Conference of Clark University, Worcester, Massachusetts. Both had to lecture and were honored with their first honorary degrees. Jung had been invited independently, because of traditional connections

between the Burghölzli hospital and Clark University through Forel's connections with his former pupil and friend Adolf Meyer, a Swiss immigrant to the United States, which played a dominant role in the formation of American Psychiatry. In the 6 weeks together with Freud during the trip to the United States, some strange personal behavior and some critical points in mutual dream interpretations inevitably revealed to Jung the limits of a friendly and cooperative relationship with Freud. Nevertheless, he continued to act for Freud as organizer and founder of the International Psychoanalytical Association, a role that he later remarked on as *collaboration à toux prix*. In 1910, he was elected president of the International Psychoanalytical Association. Shortly after Freud's provoked break with Alfred Adler in 1912, Freud challenged Jung's leadership with the organization of a 'secret committee,' consisting only of very 'confidential' followers – excluding Jung. Jung subsequently resigned as the editor of *Jahrbuch* in October 1913, and then as president of the International Psychoanalytic Association in April 1914.

In March 1909, some months before his trip to the United States with Freud, Jung quit his job at the Burghölzli clinic and opened a private practice as psychiatrist in Küsnacht, Lake Zurich. In the 1920s and 1930s, his popularity began to grow. After 1929 he was engaged in the General Medical Society for Psychotherapy (*Allg. Aerztl. Gesellschaft f. Psychotherapie*) and was an author and coeditor of the affiliated *Zentralblatt für Psychotherapie* (Berlin); after the resignation of the society's president Kretschmer in 1933 after Hitler's rise to power, Jung accepted the presidency of this organization and editorship of the affiliated *Zentralblatt für Psychotherapie*. He defended this compromising collaboration with German psychotherapists with his aim to reorganize the society as an international institution in order to help some colleagues maintain their functions, and to prevent a general abolition of psychotherapy as a medical discipline in Germany. After initial and partial success with these goals, Jung finally resigned in 1940 (Giovanni Sorge, 2012).

In 1933, Jung resumed his academic lecturing, as a lecturer for 'modern psychology' within the General Department of the Swiss Federal Institute of Technology (ETH), Zurich, he lectured courses in 'Modern Psychology' (psychology of the unconscious/the process of individuation). In 1934, he was awarded the title of professor; he resigned because of health reasons in summer 1941. From 1944 to 1945 he held a professorship in medical psychology at the University of Basel. In 1948, the Jung Institute in Zurich (later Küsnacht) was established by an international committee of some of his associates as a research and training center for Jungian analysts.

Analytical Psychology: Contribution to Science

In 1909, immediately after Jung returned from the United States, he immersed himself in archeological and mythological literature in order to differentiate his own view of the unconscious from Freud's. The result was his major work *Wandlungen und Symbole der Libido* (1912), later published in English as *The Psychology of the Unconscious* (1916). In contrast with Freud's personalistic view of the psyche – i.e., his attempt to reduce the unconscious to a hiding place of the personal, sexual conflicts of the dreamer – for Jung, sexuality was not the sole determining factor; rather, the main point was that the unconscious had an autonomous life, which reflected not only the personal, but also the common, collective history of the mind. The manifestations of the unconscious stood not only for a causal, reductive purpose, but also had a final, i.e., forward-looking, meaning. Relying on some products of automatic writing (two hymns and the dramatic myth of an Indo-American hero) produced by a young American, Miss Frank Miller (first published in 1905 in the *Archives de Psychologie*, ed. by Flournoy), Jung presented his own conception of the libido as a general 'psychic energy' with a dual nature, split into positive and negative poles with a steady flux between construction and de(con)struction. He also outlined an 'anatomy and embryology of mental development,' which followed common patterns of changing imaginary processes in the history of mankind, as well as in the personal history of each individual person. Wavering between an analysis of Miss Miller's fantasies, some hidden self-analysis, a detailed analysis of religious hero myths of humankind from Mithraism to Christianity, and an analysis of classical and romantic philosophy and literature, he developed his theory of the structure and energetic functioning of the psyche without yet coining a decisive terminology of his own.

In the years between 1912 and 1918, Jung experienced a time of personal insecurity and scientific isolation. He resigned from his post as lecturer at the university and then dedicated himself to his international practice as a psychotherapist, concentrating on his private studies and on his confrontation with his own unconscious. He documented these studies in black notebooks, elaborating on them with calligraphy and careful illustrations in a red leather–bound representative volume; in an epilogue from 1959 he stated that it was necessary to absorb the overwhelming power of his original experience until they found their way in reality with his acquaintance with alchemy, which allowed him to integrate them into a whole. This Red Book was recently published (Jung 2010, ed. by Sonu Shamdasani, 2010).

In 1921, Jung published his major book, *Psychological Types*, in which he linked his historical research with the findings of his self-analytical process. He outlined the key concepts that later became characteristic of analytical psychology such as 'types,' 'collective unconscious,' and 'individuation process.'

Jung had become interested in the question of psychological types because of the differences he perceived between Adler and Freud. With critical reference to historical material, Jung elaborated a model of typology, with eight psychological types – two main attitude types of extroverts and introverts, further subdivided by the predominance of one of four psychological functions: thinking, feeling, sensation, and intuition. While sensation conveys concrete reality through the senses, intuition conveys the hidden possibilities in the background. And while thinking leads to a judgment about the meaning of concrete reality, feeling leads to a judgment of its worth. Normally one attitude or function prevails (superior function) and the opposite (inferior) attitude or function remains undeveloped, more unconscious, and undifferentiated. The value of this model lies less in its contribution to differential psychology than in the theory of knowledge and the theory of the therapeutic process as a quest for wholeness.

From this experience of the relativity of every standpoint with respect to psychic reality, Jung highlighted the significance of the 'personal equation' as a prior condition of any psychological statements – i.e., the position that what a psychologist claimed to be true of human psychology as a whole was first and foremost a subjective confession. Additionally, he developed a conception of the therapeutic process, which involved not only becoming conscious of repressed contents of the unconscious but also integrating the psyche and developing a much more complete approach to inner and outer realities. This process of individuation involved withdrawing projections that are structured according to certain autonomous images of the unconscious (archetypes); these reflect the common history of mankind (archetypes of the collective unconscious) as well as the repressed images of one's own personal history (personal complexes). Common and ubiquitous archetypes are the shadow, the unconscious negative side of the personality; the hero, the idealized picture of the person; the anima, the animus; and the repressed female/male soul picture in men and women. This process provokes an ethical conflict in each patient; they have to take responsibility for their mental attitudes and develop a fuller approach to reality not only in ideas, but also in feelings, sensations, and intuition. As a result, the center of a person moves from the ego (the center of consciousness) toward the self (the center of the whole, individual, conscious and unconscious psyche). As therapeutic methods for this process, Jung developed active imagination (as a method of assimilating unconscious contents by several forms of self-expression) and amplification (circumambulation) of the symbols (instead of free association in Freudian analysis).

The foundation of the dynamic concept that became known as analytical psychology and the institutionalization of Jungian analysis were connected with the founding of the Psychological Club in 1916. This was made possible by the generous financial gift of Jung's American patient, Edith Rockefeller McCormick. After Jung's separation from the Burghölzli clinic and the Freudian circle, the Club reestablished an important debating forum in which he could communicate his ideas to interested patients, colleagues, and scientists. Here many of his former patients – among them his life-long special assistant and friend Toni Wolff, his secretary and the compiler of his biography, the psychologist Aniela Jaffé, and the philologist in ancient languages Marie Louise von Franz – were encouraged to take up public lecturing. In the Club he also met outstanding academics in his main subjects of interest, such as mythology, religious studies, philosophy, psychology, and archeology. Club lecturers included Karl Kerényi, pioneer in Greek mythology, the young Mircea Eliade, pioneer in the science of religions, Gershom Scholem, the German-born Israeli philosopher and historian, and other representatives of different Christian, Indian, Jewish, and Eastern religious traditions. Richard Wilhelm, missionary to China and sinologist, had a special impact on Jung. Wilhelm shared with him the old mystical Taoist text *The Secret of the Golden Flower*. It was in this text that Jung first discovered the correspondence of his individuation concept with Eastern philosophy and worked out his mandala symbolism for psychic wholeness or the self.

From 1933 on, the Club lectures and Jung's public lectures at ETH were supplemented by the Eranos Conferences, which were organized by Olga Fröbe, an English-Dutch spiritualist and scholar, every summer for a fortnight at her house at Lake Maggiore in Moscia, near Ascona, Switzerland. In the atmosphere of these meetings with contemporary pioneers and authorities in all fields of modern science and spirituality, such as the Jewish philosopher Martin Buber, the Indologist Heinrich Zimmer, the biologist Adolf Portmann, and many others, Jung presented and discussed his view of traditional Christianity and medieval alchemy, the archetypes of the collective unconscious, and the principle of synchronicity (Hakl, 2013).

An encounter with death in 1944 marked the beginning of the period of Jung's final elaboration of ideas. His main work on traditional Christianity, *Answer to Job* (1952), and his major work on alchemy, *Mysterium Conjunctionis* (Mystery of Conjunction; 1955) appeared at this time. The common principles of the reconciliation of the opposites of the dual nature of the psyche, which he had worked out in this major book, led to the final formulation of his main pioneering concept, *Synchronicity as a Principle of Acausal Relations* (1952), which he published in collaboration with Wolfgang Pauli, professor of physics at ETH. The idea of an ultimate psychoid archetype represents the connecting principle of psyche and matter, which are two aspects of the same thing and can realize themselves in both dimensions 'synchronistically.' The relative autonomy and unpredictability of the synchronistic phenomena correspond with the new findings of subatomic and cosmic physics and hint toward a metaphysical order to which both the psyche of the perceiving person as well as nature itself submit.

Contemporary Influence

In contrast with Freud, who gave the impression that psychoanalysis "may be likened to Athena's springing forth fully armed from the head of Zeus" (Jones, 1953–57), Jung always tried to trace back his ideas to older, universal traditions. His pioneering work was the rediscovery of an uninterrupted chain of psychic manifestations and spiritual traditions from antiquity, gnosticism over alchemy to the present. His early claim for a constructive, forward-looking meaning in unconscious manifestations led to some changes in early psychoanalytic treatment that are now common in psychotherapy, for instance, the symmetrical setting (instead of the patient lying down), focus on present conditions as responsible for the outbreak of neurosis, and focus on transference and countertransference as the crucial point for the change of mental attitude. In addition, Jung's conception of the spiritual nature of psychic life influenced the later transpersonal and humanistic schools of psychotherapy. His concern with spiritual mystical traditions often led to controversial claims that he himself was a mystic, selling false dreams of spiritual redemption. The alleged evidence of the most recriminatory voice (Noll, 1997) has been traced back to an obviously misidentified and misinterpreted document and shown to be fallacious (Shamdasani, 1998). Jung emphasized that he had no 'doctrine' to offer, but rather some methods of looking at facts, phenomena, and natural laws. His approach to these facts is empirical in the sense of a critical reflection on the nature of all

experience that relates to self-experience and the nature of the perceiving psyche.

This view, which valuates the psyche as 'the mother of all science and arts,' reveals its special importance in the approach to religious phenomena. The unconscious psyche with its autonomous operators (collective archetypes) reflects the numinous, awful, frightening, and timeless spirit in changing images that correspond to changing religious images from ancient times to the present. In differentiating between religious images and religion itself, Jung pointed to the inner experiences open to everyone independently of every external belief system.

Jung received numerous honorary degrees: in 1909 the first honorary degree, from Clark University Worcester, Massachusetts, USA; in 1936 from Harvard University, Cambridge, Massachusetts, USA; in 1937 from Hindu-University Benares and the universities of Allahabad und Calcutta/India; in 1938 from Oxford University, UK; in 1945 from the University of Geneva, Switzerland; and in 1955 from the Swiss Federal Institute (ETH), Zurich.

Abstract

This article describes the jury, including changes over time and variations in the use of lay juries in the United States and internationally. It considers the jury not only as a decision maker, but also as a political institution. The topics covered include: methodological issues in studying the jury, how jurors evaluate evidence, jury composition, jury size and decision rule, individual differences, effects of the media, jury competence, jury instructions, deliberations, a comparison of the jury with other potential triers of fact, and reactions to jury trial and the reform movement.

The jury is a group of laypersons recruited by the legal system to resolve a dispute. In contrast to professional judges, jury members are amateur and nonrecurring decision makers. They are selected from the community at large rather than for their legal expertise, and they adjudicate disputes only on occasion rather than on a routine basis. The jury is both a cultural icon and a popular scapegoat, praised as a champion of democracy and denounced as incompetent or biased when it reaches an unpopular verdict. Empirical research offers a more measured view of the jury, revealing a motivated set of decision makers, often admirable in the way they handle the complex and contentious disputes they are asked to resolve, but always human in their struggles to deal with limited resources and imperfect information and to balance competing values in reconstructing events and assessing mental states.

The ideal jury has many potential roles: a thorough and impartial judge of the evidence presented at trial, a faithful representative of the community from which it is drawn, an obedient follower of legal instructions, a protector of citizens against the power of the state, and a repository of common-sense justice that tempers the harsh hand of the law. Critics charge that juries fail to fulfill one or more of these roles. Behavioral scientists who study the jury find some variation from this set of ideal roles, in part because the roles can be inconsistent with one another, in part because the jury's cognitive and motivational characteristics influence its behavior.

Jury Variations

The jury has gone through numerous incarnations over time and exists internationally in a variety of forms. The medieval jury was limited to male property owners, who came to court with extensive knowledge about the case. They acted as witnesses, investigators, and tribunal, determining both the facts and the law. The modern American jury is drawn from the citizenry at large, with the parties entitled to eliminate some prospective jurors if they have preconceived notions about what the verdict should be before the trial begins. Jurors generally are expected to absorb and evaluate the evidence presented at trial, apply the law as it is described in the judge's instructions, deliberate until they reach a verdict or an impasse, and disperse without personal consequences at the end of the case, except for the occasional inquiries of the American press in high-profile trials. The right of citizens to have both criminal and civil controversies resolved by groups of ordinary fellow citizens is guaranteed by the US Constitution and by every state constitution.

Although the majority of criminal trials decided by a jury occur in the United States, juries are also part of the criminal justice system in the countries of the British Commonwealth. Moreover, a new and renewed interest in juries is taking place internationally (e.g., in Argentina, Spain, Russia, and South Korea), reflecting the perception that citizen adjudication in the justice system is a mark of a democratic government. In civil cases, jury trials occur almost exclusively in the United States and Canada. England eliminated juries in most civil cases by the 1930s, retaining the civil jury primarily in defamation cases. Most modern juries are small, compared to the ancient Greek jury of several hundred that tried Socrates. For example, some American jurisdictions have juries of six. All states with the death penalty, however, use a jury of 12 for capital cases. The South Korean jury, introduced in 2008, has five, seven, or nine jurors depending on the seriousness of the offense.

Although the jury is prominent in discussions about the American legal system, legal disputes are infrequently resolved by the verdict of a jury, even in the United States. Most criminal cases in the United States end in dismissals or guilty pleas; most civil cases are dismissed or settled. An estimated 150 000 jury trials occur annually in state courts and an additional 5000 in federal courts (Mize et al., 2007). The influence of the jury extends far beyond the trials it actually decides, however, as litigants and attorneys anticipate what a jury would do if asked to resolve the dispute. Inaccurate expectations are common, based on impressions gleaned from high profile but idiosyncratic trials and from trials resulting in unusually high awards that attract media attention. The absence of direct and reliable feedback on what would have happened if a jury had actually decided a case that was resolved without trial provides little opportunity to correct misimpressions. The value of the jury as a signal of likely trial outcomes has been threatened in recent years by the drop in the percentage of both criminal and civil cases that culminate in trials.

Political Roles of the Jury

In addition to adjudicating disputes, the jury is a potential source of legitimacy for the legal system. To the extent that the

jury is viewed as representing a fair cross section of the community, its verdict is likely to be seen as the product of fair consideration and can carry a degree of legitimacy that the decision of the judge, as an employee of the state, may lack. Even when its verdict is unpopular and even if observers believe that the jury does not fairly represent the community, the jury acts as a lightning rod, insulating the judge and other parts of the state legal system from criticism. American opinion polls consistently show that a majority of citizens support the jury system.

The jury also can act as a conduit for community standards. For example, in evaluating a claim of self-defense, the jury must determine what a reasonable person would be expected to believe, as well as what the particular defendant did believe. Although the jury is charged with applying to the facts the law it receives from the judge, the self-defense example illustrates the fuzziness of the division between law and facts. The jury must often inject its understanding of appropriate standards into its fact finding even while scrupulously following the instructions that the judge provides.

An additional political role for the jury is its educative function, identified by De Tocqueville as the jury's great strength. Surveys suggest that more than half of American adults have had some personal involvement with the courts, and of this subgroup, half have served on a jury. Citizens also receive information and misinformation on the courts from other sources, including the media. The extent to which jury service provides additional or corrective information is unclear, but jury experience tends to make jurors feel more positive about the jury system.

Finally, experience as a juror has a wider effect on the citizens who serve. Recent evidence has shown that it promotes civic engagement and political participation (e.g., prior jurors showed an increased likelihood of voting, Gastil et al., 2010).

Methodological Challenges in Studying the Jury

Study of the jury is a particularly thorny project because the jury speaks publicly only to deliver its verdict: deliberations occur outside the presence of any nonjuror. Although not all jurisdictions have legislation that bars access to jury deliberations, there have been only a few instances in which deliberations have been observed or recorded, and only one systematic study of real jury deliberations (Diamond et al., 2003). Researchers have used a variety of indirect approaches to study juries, each with strengths and limitations: (1) archival studies of jury case characteristics and verdict patterns, which provide information on large samples of cases, but can only reflect the limited variables that have been recorded and may, as in the case of commercial jury verdict reporters, have systematically biased samples, favoring, for example, the publication of cases with large awards (Lee and Waters, 2011); (2) posttrial surveys or interviews that question jurors about the actual process of reaching a verdict, but must depend on what jurors noticed, accurately recorded, remember, and are willing and able to report; (3) surveys of other trial participants, such as judges and attorneys, who are informed court observers, but have only indirect information on jury behavior; (4) field experiments, which can offer strong evidence on the impact of a legal reform like juror note taking, but provide little information on process and require unusual cooperation to implement correctly; and (5) mock jury experiments, the most widely used method for studying the jury. A key strength of mock jury experiments is that they combine control with the opportunity to examine the process of decision making. The extent to which behaviors observed in these experiments mirrors the behavior of real juries is hard to assess. Some evidence, however, shows substantial correspondence between verdict results and simulations that vary in realism, suggesting that not all differences will affect the results (Bornstein, 1999).

How Jurors Evaluate Evidence

The traditional legal model of the jury trial portrays jurors as passive recipients of the evidence and legal instructions. Yet even legal instructions send a double message: decide the case based solely on the evidence presented in court, yet use commonsense and experience in reaching a decision. Empirical studies of jury behavior find jurors to be active processors of incoming information. Jurors enter the courtroom with preconceptions and expectations that affect the way they react to evidence. They actively search for causal explanations to make sense of what they are hearing and seeing, and they fill in gaps and interpret ambiguities in ways that influence their decisions. Although it is possible to imagine a method of decision making in which a decision maker gives each piece of evidence a value and a weight, and then combines the results algebraically to reach a verdict, this mechanical approach does not describe the decision-making process of jurors. Nor have more elaborate mathematical modeling efforts (e.g., Bayesian accounts) captured what jurors do.

A more cognitively grounded, and more widely accepted, model of individual juror decision making is the story model. According to this model, jurors employ an explanation-based judgment process. They construct a summary, mental picture of what decision-relevant events occurred and the causal relations among them (Pennington and Hastie, 1986). The construction of a cognitively coherent explanation is a central focus of related decision models as well (e.g., Simon, 2004). Jurors select, organize, elaborate, and interpret the evidence, drawing inferences to connect the pieces to develop an explanation-based narrative. Each decision maker utilizes a general comprehension strategy for understanding human action that includes some features that legal doctrine may not consider relevant, like the defendant's motive (Nadler, 2012).

Some models of jury behavior generated in the laboratory assume that jurors begin deliberations with clear verdict preferences. Yet when jurors begin their deliberations, many hold only tentative views about the most plausible version of what happened and a rough understanding of the legally relevant criteria for reaching a verdict. As a result, the deliberation process often involves an early consideration of the content of the jury instructions (Diamond et al., 2012). Overall, the jurors attempt to develop the most plausible reconstruction of the events by pooling their assessments of the incomplete and conflicting stories that the witnesses tell. They are sensitive to apparently inconsistent behavior and testimony, within and across witnesses.

Jurors in a minority of cases begin their deliberations in agreement; in the majority of cases, there is more than one way to view the evidence. Deliberations may begin with a vote "to see where we stand" or, more often, with an attempt to construct a group understanding of the evidence. Despite the common image that the jury nearly always takes a vote at the beginning of deliberations, early calls for a vote are frequently derailed by discussion about the evidence or the instructions. Moreover, the longer the trial, the longer the prevote discussion, suggesting that a heavier evidentiary load requires more processing time before jurors attempt to reach a verdict.

Jury Composition

The modern American jury is far more heterogeneous and representative of the citizenry at large than was the early English jury or even the jury in the early twentieth century. Nonetheless, the jury is not a random sample of citizens. It is the product of a multistage selection process that typically begins with a list of potentially eligible jurors drawn from voter registration lists and often supplemented by individuals holding drivers' licenses in the general geographic area where the court sits. Prospective jurors may be excused from jury service on the basis of hardship, but losses also arise from geographic mobility, a failure to update the lists, and nonresponse by prospective jurors to court summons. The loss of prospective jurors in the qualification and summons process results in a systematic underrepresentation of minorities, younger individuals, and those at lower income levels.

The final stage in jury selection occurs when prospective jurors are brought into the courtroom and questioned to determine whether they will serve in the particular case. Those who clearly express preconceived notions about what the verdict in the case should be or those with clear conflicts of interest are excused by the judge, known as a challenge for cause (Rose and Diamond, 2008). In addition, the parties can excuse a limited number of prospective jurors without giving a reason (the peremptory challenge). The US Supreme Court has ruled that peremptory challenges based on race or gender are constitutionally prohibited, but evidence suggests that the prohibition fails to eliminate racially and gender motivated challenges (Sommers and Norton, 2008). Courts generally do not require much justification from the party initiating the peremptory challenge when the opposing party charges that the challenge was improperly motivated. Also, the small number of challenged jurors in the typical trial means that an attorney can generally identify a unique and nondiscriminatory reason for each challenge.

The result of this variety of shaping and sometimes crosscutting forces is that juries tend to be somewhat more educated, wealthier, and older, and less likely to include a representative number of minorities than the distribution of these groups in the adult population. The selection process that occurs before the jurors enter the courtroom is primarily responsible for the difference between the composition of the American jury and the adult population as a whole. Although the difference is likely to persist, the American jury today is more representative than it has ever been. Moreover, jury participation is extensive. Surveys indicate that 25% of American citizens are likely to serve on a jury trial at some point in their lives. That percentage may drop with the decreasing number of jury trials, but because most courts have reduced terms of jury service, often limiting the term to one day of service or one trial, the distribution of lifetime service among citizens may not change.

Jury Size and Decision Rule

Traditional English and American juries consisted of 12 members who were required to reach a unanimous verdict. Some American jurisdictions now permit juries with as few as six members and nonunanimous verdicts of 9:3 or 10:2; England permits a 10:2 verdict if the jury has been unable to reach unanimity within a specified period of time. Reducing jury size decreases the representation of minority perspectives on the jury and increases the likelihood of an aberrant jury verdict. A majority decision rule tends to reduce the rate of hung juries and to shorten deliberations because jurors in the majority do not need to gain the support of all jury members, but hung juries are most likely to occur when the jury has more than one or two holdouts. Jury deliberations under a majority decision rule can be less thorough because the deliberators can arrive at a verdict without considering the reasons why there is disagreement among the members of the jury. Reflecting this evidence, the 2005 American Bar Association Principles on Juries and Jury Trials endorsed twelve-member juries and a unanimous decision rule.

Individual Differences

Attempts to predict juror verdict preferences from background characteristics have generally been able to explain only a modest amount of variance in outcomes (Lieberman and Sales, 2007). Demographic characteristics like gender, race, and age generally account for very little of the variation in response. Attitudinal characteristics can be more powerful, albeit also modest, predictors. Expectations, beliefs, and values affect the way that jurors react to evidence. In that respect, jurors are no different from any other decision makers, because people ordinarily scrutinize more carefully and are more likely to reject information that is inconsistent with their beliefs and expectations, because it is generally easier for people to remember theory-consistent information than theory-inconsistent information, and because ambiguous information tends to be interpreted as theory consistent.

Some types of cases are more likely than others to implicate strongly held beliefs or values. A primary example involves murder punishable by the death penalty: even among jurors willing to impose the death penalty in some cases, the strength of their support for the death penalty can strongly influence the likelihood that they will vote for a death sentence. Moreover, those who support the death penalty are more likely to find a capital defendant guilty of murder.

Juries and the Media

The American constitutional right to a free press has always permitted the media to provide the public with pretrial

information, putting the constitutional rights to a free press and to a fair trial potentially at odds. Traditionally, this media exposure did not occur in countries like Canada and Great Britain where the press is prohibited from writing about impending trials. The Internet has changed all of that. Now that nontraditional media sources, including individual bloggers, can use the Internet to swiftly and widely disseminate both accurate and inaccurate information about cases and parties, both interested and casual users of the Internet may receive these communications. If these sources include potentially prejudicial information about issues like a defendant's alleged confession, the danger is that this exposure will affect the expectations and beliefs of prospective jurors. Although some research on traditional pretrial publicity suggests that the effects are generally small, there is currently little systematic research on the effects of new media on the jury.

Attorneys too, when they have access to the names of prospective and sitting jurors, can use the Internet to conduct background research on the jurors. The line between due diligence and intrusive prying is unclear at this point, as is the impact of gathering this information. In the twenty-first century world of cable and the Internet, limited exposure may be a thing of the past. Moreover, the new technology has spawned legitimate concerns about the potential interactions between jurors and media sources on the Internet, both during and before trial, as well as juror uses social media to communicate with sources of potential influence outside the trial setting. Courts have responded with increasingly specific judicial admonitions and warnings, but it is not yet clear how effective these efforts are likely to be and, to the extent that they are not effective, the consequences for trials. Use of the Internet has grown exponentially, but increasing sophistication about the potentially misleading content available on the Internet may reduce its impact. Nonetheless, the Internet has reduced the effectiveness of moving the location of a high-profile trial as a way to counteract potential effects of pretrial publicity.

Competence, Including Reactions to Experts

Both criminal and civil trials increasingly involve the testimony of experts who present technical and scientific evidence (e.g., DNA analysis, econometric modeling, epidemiological and toxicological research; Vidmar and Diamond, 2000–2001). Such complex evidence presents a challenge for the experts who must communicate with a lay audience, for the judge who acts either as a gatekeeper in ruling on which experts can testify and what they can say or as the trier of fact, and for the lay jury.

Although jurors typically exert considerable effort in trying to understand the content of expert testimony, questions arise about the ability of jurors (and judges) to evaluate technical and scientific evidence. Jurors (and judges) can be confused by expert testimony, but that confusion can often be reduced or avoided if the expert is also a good teacher. Moreover, jurors frequently express skepticism about the trustworthiness of experts presented by parties within the adversary system and, although cross examination may not be as powerful a corrective mechanism as traditional legal doctrine presumes (Levett and Kovera, 2009), jurors adopt reasonable strategies to evaluate expert credibility. In addition, juries can and do draw on the expertise of their most competent members, some of whom may have scientific or technical backgrounds, to assess the strength of the evidence, providing a resource that is unavailable to the trial court judge.

Reactions to the Law, Including Nullification

Jurors are instructed to apply the law as the judge describes it to the facts as the jury finds them. Juries may not always follow the instructions, but the primary cause of that failure is the inadequacy of the instructions rather than a willful disregard by the jury. Jurors may fail to follow the judge's instructions on the law if they are either unmotivated or unable to apply the instructions, but they typically see themselves as obligated to apply the law and spend a significant portion of their time during deliberations discussing the law. Nonetheless, legal instructions often fail to provide jurors with helpful legal guidance. The major goal in writing jury instructions on the law is to produce language that will accurately reflect the relevant law so that appellate courts will find the instruction acceptable. Insufficient attention is generally given to ensuring that the meaning of the instruction is clearly communicated. In addition to legal jargon, poor communication may result not only from legal jargon. It may also occur if omissions leave jurors without guidance on some legal issues or if structural problems arising from the piecemeal construction of jury instructions leave jurors confused about how the pieces fit together (Diamond et al., 2012). Comprehension of instructions can be significantly improved by using plain language, simplifying sentence construction, providing definitions for technical terms, and specifically correcting jurors' inaccurate expectations and misconceptions.

Although the most common source of jury deviations from legal standards is a failure of the legal instructions to convey clearly what the appropriate legal standard is, jurors also may deviate from the path outlined in the instructions due to cognitive or motivational biases. For example, jurors admonished to disregard particular information may find it difficult to do so. Other legal instructions may ask the jurors to engage in mental gymnastics – for example, to use a defendant's criminal record only to assist in evaluating his credibility, but not as evidence of bad character; to forget that they learned about damaging evidence that the judge ruled inadmissible – and jurors may be unwilling or unable to perform the required cognitive adjustments. It is unclear whether these failures are significantly less likely when the trier of fact is a judge. Some recent studies of judges suggest instead that cognitive biases represent heuristic patterns of using information that neither juries nor judges can be expected entirely to overcome.

Finally, jurors may depart from the judge's legal instructions when the application of the legal standard to the particular case so substantially violates the jurors' sense of justice that they are persuaded to temper the letter of the law in that case. Although such deviations are rare, explicit jury nullification plays a central role in conceptions of the appropriate role of the jury and has been a source of extensive debate. Courts have long recognized the power (as opposed to the right) of the jury to nullify, but both courts and some empirical evidence raise concerns about whether instructing juries about that power invites unwarranted rejection of legal standards (Horowitz et al., 2006). When jurors

are explicitly told that they have the right not to apply the law as the judge describes it, they are more willing to reach verdicts that avoid the literal application of the law.

Deliberations

Deliberations resulting in a group verdict distinguish the jury from its chief alternative, the trial court judge, in two ways. By requiring agreement from multiple jurors, the jury verdict in principle reduces the likelihood that the decision will represent an idiosyncratic view of a single deviant decision maker. Moreover, in theory, deliberations give the jury an opportunity to profit from the resources of its multiple members, to pool its knowledge and sensibilities, and to resolve differences, ultimately producing a verdict that reflects more than what could be achieved either by a single decision maker or by mechanically combining or averaging the preferences of the individual members.

The extent to which deliberations actually do affect jury verdicts, however, is in dispute. Early scholars (e.g., Kalven and Zeisel, 1966) suggested that jury verdicts simply reflect the position of the majority before deliberations begin. The picture they presented was consistent with the verdict-driven jury that takes an immediate vote to see where each juror stands and then focuses its attention on persuading the minority to join the position initially held by a majority of the jurors. When a vote is immediate, it is likely to reflect predeliberation preferences. When a discussion of the evidence precedes a vote (the so-called evidence-driven jury), that vote will be affected by any changes that have occurred as a result of the discussion. Although faction size is a strong predictor of verdict (Devine, 2012) and most juries probably do end up with a verdict that reflects the majority that is visible by the time most of the jurors have expressed a verdict preference in deliberations, recent research suggests a more prominent role for deliberations in determining trial outcomes (e.g., Hans et al., 2003). Moreover, the outcome of deliberations is less predictable when a majority position is less likely to emerge because there are multiple verdict choices or in civil cases where damages are at issue.

Civil Liability and Damages

Civil juries are sometimes viewed as proplaintiff when it comes to liability, although there is little evidence to support the claim that they are more likely than judges to find the defendant liable (Greene and Bornstein, 2003). Although jurors do hold corporations to a high standard of behavior, the standard primarily arises from an expectation that corporations are better able to control their behavior than an individual might be (Hans, 2000). On the issue of damages, the pattern of jury behavior is less clear. Compensatory damage awards generally vary with the severity of the injury (i.e., vertical equity), but there is some evidence that plaintiffs with small losses tend to be overcompensated and those with large losses tend to be undercompensated. Compared to special damages (e.g., lost wages, medical expenses), the difficult-to-measure general damages (e.g., pain and suffering), show greater variation in the amounts awarded for injuries at the same level of severity (i.e., horizontal inequity). In the absence of a standard for the 'correct' amount that will compensate for pain and suffering, some scholars have suggested that juries be supplied with information on the pattern of pain and suffering awards in previous jury trials involving similar injuries. Although the problem of defining 'similar injuries' remains, this additional information may reduce some unwarranted disparity across cases.

Civil juries are sometimes instructed that they can award damages for punishment and deterrence (i.e., punitive or exemplary damages) as well as damages for compensation. Punitive awards most frequently occur in cases involving intentional harms and financial rather than physical harms. They are rare, but they are the subject of great controversy, in part because there is little agreement on what award levels are appropriate to suitably punish, as well as deter, these harmful behaviors.

The Jury vs Alternative Triers of Fact

Discourse on the performance of the jury frequently ignores a basic reality of legal systems: in evaluating the jury, the relevant comparison is not some hypothetical ideal decision maker, whatever qualities such a model decision maker would have. Rather, the appropriate comparison is the human alternative or set of alternatives that might be used in the jury's stead. Alternatives to the jury include professional, legally trained judges, and mixed tribunals composed of laypersons and legally qualified professionals. Studies that have compared the reactions of laypersons and legal professionals to the same criminal trials indicate, first, high levels of agreement on verdict (74–90%), and, second, a greater inclination to acquit by laypersons when they disagree with the professionals (e.g., Eisenberg et al., 2005; Kim et al., 2013). In addition, agreement rates do not vary with the complexity of the trial, suggesting that disagreement is not a product of an inability of the laypersons to understand the evidence.

The few studies that compare the process of decision making by judges and jurors show a surprising correspondence even in response to case characteristics that might be expected to influence laypersons more than professionals (Robbenolt, 2005). The assumption of the legal system that judges can 'compartmentalize' and discount legally inadmissible information, and avoid being influenced by it, appears to be an inflated expectation. Both laypersons and professional judges fail to disregard inadmissible evidence, are influenced by outcome information in their judgments about the probability of that outcome (the hindsight bias), and are reluctant to find for the plaintiff when presented with statistically based evidence. If judges are influenced by inadmissible evidence, the jury trial may provide an effective way to avoid burdening the trier of fact with much of the potentially biasing information that judges must regularly confront. In addition, the trial judge in a jury trial retains the power to override a conviction by a jury if the judge determines that the conviction is unwarranted by the evidence, providing a rarely used but available extra protection for the defendant in a criminal jury trial.

Reactions to Jury Trial and the Reform Movement

As a lightning rod for popular debate, the jury is regularly the subject of calls for reform. Some reforms, such as those permitting jurors to submit questions for witnesses during the trial, do not assume that juries are failing to perform adequately but rather are designed to assist them in reaching well-considered judgments, to improve the comfort of the conscripted citizens who serve as jurors, and generally to optimize jury performance and juror satisfaction (Dann, 1993; Diamond et al., 2006). Other proposed reforms aim at reducing the right to jury trial or limiting the power of the jury, such as calls for a complexity exception to the right to jury trial in civil cases and for legislative caps that place a ceiling on jury awards. High-profile trials resulting in unpopular verdicts have stimulated some of the proposed changes in the jury system as have the concerted lobbying efforts of particular interest groups (e.g., the insurance industry). It is likely that calls for reform of all kinds will continue to follow the jury. The real question is whether the increasing scholarly literature on jury behavior will inform popular and political discussions about the jury.

Just City

Susan S Fainstein, Harvard University, Cambridge, MA, USA

Abstract

The term 'the just city' refers to a body of work that develops a theory of urban justice and derives criteria from it to apply to urban policy. Until recently, critical urban studies identified injustices within the urban realm but, with the exception of the work by David Harvey and Henri Lefebvre, did not explicitly create a normative theory to depict what constitutes justice. Many of the studies with an urban political economy perspective focused on property development and urban social movements, primarily within wealthy Western countries; the criteria on which they based their critique of urban governance and flows of capital remained implicit. In the 1990s and thereafter, urban scholars began to address the topic of justice explicitly. Particularly influential was Iris Marion Young's book, *Justice and the Politics of Difference*, which defines justice as the absence of forms of domination and which moves beyond Marxist-inspired political economy to identify nonmaterial forms of injustice arising from the marginalization of groups. Building on her argument, many scholars named diversity as a chief component of justice. One important strand of thought, based on the writings of Jürgen Habermas, emphasized communicative rationality. Susan S. Fainstein, in her book *The Just City* considers that there are three major components of urban justice: democracy, diversity, and equity, with priority to be given to the latter.

The Just City is a book written by Susan S. Fainstein that was published in 2010. It develops a theory of urban justice and a set of criteria to apply to urban policy derived from these principles. The effort builds on a body of work in geography, planning, politics, and sociology that counters the dominant approach in social science by which individual decisions and market processes constitute the primary explanatory and normative framework for social–spatial description.

Development of Concept within Urban Studies

Although the subject of justice has always been a major topic within political philosophy, contemporary social scientists largely avoided normative statements, adhering to a positivist methodology that aimed at scientific rigor. In the 1960s and 1970s, however, dissenters contended that the ostensibly factual basis of empirical analysis disguised ideological support for an unjust status quo, even while not explicitly developing a concept of justice (Sayer and Storper, 1997). Those attacking injustice within cities sought to demonstrate how spatial manipulation underlay the disadvantages suffered by residents of poor neighborhoods. The theoretical basis for much of the discussion about urban justice was developed by the French theorist Henri Lefebvre (inter alia, 1968, 1970, 1996, 2003), who defined space as being constituted by social relations rather than, as had been the case until the 1960s, by its territorial, physical, and demographic characteristics. Under this reading, space ceased to be a container of buildings, population, and production but instead became a constituent of the relations of production and reproduction and a contributing source of inequality and by implication of injustice.

During the 1970s, a group of theorists who were influenced intellectually by Lefebvre and practically by the uprisings that occurred in European and American cities during the preceding decade broke away from the types of analysis constituting the mainstreams of their disciplines and applied a political--economic epistemology to the study of urban development. Many of these thinkers were based in the Research Committee on the Sociology of Urban and Regional Development of the International Sociological Association (RC21), which was established in 1970. Although the auspices of the research committee were within the discipline of sociology, membership was highly interdisciplinary, and many of the founders of the research committee were neo-Marxists who aspired to inject a spatial element into Marxist theory. Among the founders of this group were Manuel Castells, Michael Harloe, David Harvey, Peter Marcuse, Enzo Mingione, Chris Pickvance, and Edmond Preteceille. Hailing from a number of different, primarily European countries, these scholars developed a critical approach to the relatively recent field of urban studies and started a journal, the *International Journal of Urban and Regional Research*, edited for many years by Michael Harloe, which published articles reflecting their viewpoint.

The two books that proved most influential in setting the course of later work were Manuel Castells's *La Question Urbaine* (1972, 1977) and David Harvey's *Social Justice and the City* (1973). Castells identifies the city as the site of social reproduction and thereby moves the emphasis in Marxist analysis of cities toward questions of distribution, in particular to the role of the local state in providing the means of subsistence or collective consumption (i.e., goods and services provided outside the market, usually under the aegis of state bureaucracies). Within this framework, the important societal agents became state actors and urban social movements demanding benefits from bureaucratic institutions rather than mobilized workers seeking to take over the means of production. In *Social Justice and the City*, Harvey, who is generally considered to be the most prominent geographer of the latter half of the twentieth century, describes how he moved away from more conventional analysis to a focus on the relationship between urban space and the social situation of residents. He argues that space, social justice, and urbanism must be understood in relation to each other and that "it is, of course, the power of Marx's analysis that it promotes such a reconciliation among disparate topics" (1973, p. 17). For both Castells and Harvey, the crucial issue for study

is how power relations (as determined by the interaction between state authority, economic ownership, and urban residents) affect urban outcomes and, in particular, how spatial relations reinforce injustice. Unlike Castells, who limited himself to analysis rather than advocacy, Harvey openly stated that his project was achieving a more just society (even while maintaining that justice could not be defined as an abstract principle). He did not, however, identify an agent of change beyond a general reference to the role of the working class. Rather, Harvey focused on the logic of capital, especially as it circulated through the financial and real estate sectors in cities, regions, and the globe. He pointed to contradictions within the capitalist economic framework and saw these contradictions as undermining the system. Harvey uses the term the 'spatial fix' to describe how capitalists shift investment across spatial boundaries so as to circumvent crises of profitability in any particular place. Castells (1983), who regarded social movements rather than political parties or classes for themselves as the principal force for change, in a later work developed a theory of grassroots movements.

These two foci – property development and community struggle – developed by Castells and Harvey became the preoccupations of later works by a variety of authors concerned with urban justice. Many of them were inspired by insurgent movements against allegedly value-free social science within the traditional academic disciplines. Although these later scholars continued to work within the framework of a critical political economy, they did not usually define themselves as Marxists. Even those who, like Castells, began as Marxist theoreticians, with the exception of Harvey, typically moved away from Marxist terminology and became theoretically eclectic. At the same time, many geographers retained an allegiance to Lefebvre, especially to his concept of the right to the city (see, inter alia, Purcell, 2008; Smith, 2003; Soja, 1989), which became equated with a transcendent ideal of justice that went beyond distributional issues to the right to participate in the creation of the city (Marcuse, 2009).

Foundations for Normative Criteria in Empirical Research

The discussion around urban justice in the terms described above arose primarily among researchers within wealthy, Western countries, who in particular were reacting against the depredations of state-sponsored programs for highway construction and urban redevelopment (or, in British terminology, regeneration) that had the effect of destroying the housing and communities of low-income communities. Among the many works describing such involuntary displacement are Herbert Gans's *The Urban Villagers* (1962), which chronicles the demolition of Boston's predominantly low-income Italian West End and its replacement by luxury apartment buildings; Jane Jacob's *Death and Life of Great American Cities* (1961), which calls redevelopment programs the rape of cities; Alan Altshuler's *The City Planning Process* (1965), which depicts the annihilation of an African-American neighborhood to allow for an expressway; and Parkinson, Foley, and Judd's *Regenerating the Cities* (1988), which presented a group of case studies drawn from UK and US urban renewal experiences. Initial concerns over the razing of neighborhoods and their replacement by high-end residential or commercial structures shifted to the identification of economic development approaches subsidizing wealthy property developers (Fainstein, 2001; Le Galès, 1991) and to the transformation of neighborhoods achieved through gentrification (Smith and Williams, 1986; Hamnett and Randolph, 1988; Lees et al., 2008).

Another thread of research picked up on the question of agents of change. A number of works traced the effects of urban social movements (Piven and Cloward, 1971, 1977; Fainstein and Fainstein, 1974; Mayer, 2010). Paul Davidoff (1965) argued that planners should be advocates for disadvantaged groups, and Norman Krumholz (Krumholz and Forester, 1990) contended that even planners employed by governments could engage in 'equity planning' for the benefit of poor and minority communities. Urban social movements made demands for citizen participation and 'community control' (Altshuler, 1970), contesting the notion that experts were the best judges of the public interest.

Critical analysis of urban change was, as noted above, carried out in an interdisciplinary framework. Nevertheless, scholars from different disciplines had different emphases. Geographers used the term 'uneven development' to depict the way in which capital flowed in and out of different parts of the city, region, and nation, continually creating relative wealth and relative poverty (Smith, 1991). Sociologists particularly noted the persistence of segregation by race and class (Massey and Denton, 1993) and the social basis of power within cities (Logan and Molotch, 1987). Political scientists analyzed power differentials and identified progrowth coalitions of business elites as the force behind the destruction of low-income communities and the subsidization of commercial interests (Mollenkopf, 1983; Stone, 1989). Planners were especially concerned with the exclusion of low-income communities from the planning process (Arnstein, 1969). As will be discussed below, many of these works assumed a normative standard of justice against which public actions were measured but did not usually make this standard explicit.

Spatial Justice in the Developing World

The literature so far discussed critically examined the relationship between spatial phenomena and social justice within the context of cities with large economic surpluses. Concern with the distributional effects of policy evolved from the perception that in prosperous metropolitan areas there was more than enough wealth to allow everyone a decent standard of living. Within poor countries, the issue of spatial justice takes on a different form. Dependency theory attributes continued widespread poverty to the domination by core countries of peripheral areas. Theories of uneven development, originally referring to flows of capital among and within cities in the developed world, are applied to the relations among nations. While framed also within an understanding that spatial relations and the real estate industry contribute to immiseration of low-income communities, the focus of scholarship is on the region and the nation rather than the city (see, e.g., Wallerstein, 1974; Amin, 1976; Cardoso and Faletto, 1979).

Making the Implicit Explicit

Until the 1990s, much urban literature has as a subtext a critique of injustice and a normative standard on which the critique was based, but only David Harvey actually uses the word 'justice' in developing his analysis, and he manifests considerable ambivalence toward the term. On the one hand, he declares, "We cannot do without the concept of justice for the simple reason that the sense of injustice has historically been one of the most potent seedbeds of all to animate the quest for social change" (Harvey and Potter, 2009, p. 41). On the other, he sees all concepts of justice as embedded in power relations and rejects "idealist specifications of rights and of justice" (Harvey and Potter, 2009). It is not clear, however, from where oppositional concepts derive if not from idealist specifications, albeit filtered through existing social practices.

During the 1990s, urban scholars finally began to address the topic of justice explicitly. Iris Marion Young, although a philosopher by discipline, taught in an urban planning department at the University of Pittsburgh. Her book, *Justice and the Politics of Difference* (1990), specifically addresses the issue of justice within the city. Her identification in that book of injustice with types of oppression led her to define justice as the absence of forms of domination (exploitation, marginalization, powerlessness, cultural imperialism, and violence), an approach adopted in a number of subsequent works. Harvey's concern with social justice and the city prompted a conference and then the publication of a book (Merrifield and Swyngedouw, 1996) on the occasion of the twentieth anniversary of his *Social Justice and the City*. The intent of this initiative was to bring to the fore the issue of social justice which, the editors opined, had been "relegated to the hinterlands of academic inquiry" (1996, p. 2).

Considerable effort has been made since the beginning of the new millennium to define justice and prescribe approaches to realizing it within the urban context. Where earlier scholars had not specified the value system underlying their critiques or offered prescriptions for more just policies, they began to hold conferences, produce books, and start journals that named justice as their objective (e.g., Marcuse et al., 2009; Hayward and Swanstrom 2011; Brenner et al., 2012; the French journal *Justice Spatiale/Spatial Justice*) In doing so, they looked to political philosophy for guidance since philosophers, unlike social scientists, have long discussed the lineaments of a just society. Mostly, however, philosophers avoided making practical recommendations for its realization.

The most important twentieth-century book developing a theory of justice is by John Rawls. Famously, Rawls argued that the allocation of goods in a society should be governed by the 'difference principle,' whereby policies should only improve the situation of those better off when "doing so is to the advantage of those less fortunate" (Rawls, 1971, p. 75). Rawls posits that in the "original position," behind a "veil of ignorance" that prevents individuals from knowing what will be their ultimate position in society, they will opt for a more egalitarian distribution of goods. By this logic, egalitarianism is a rational choice for individuals. Although Rawls does not address justice within the city, his argument for a just society defined by greater equity stimulated much later work within political philosophy that in turn filtered into urban social science. In particular, the writings of Jürgen Habermas as well as Henri Lefebvre and Iris Marion Young influenced urban theorists.

Choosing justice as the norm for urban policy represents a reaction to the growing inequality and social exclusion arising from the use of neoliberalism as the template for public policy (Brenner and Theodore, 2002). 'Neoliberalism' refers to the doctrine that market processes produce the most efficient allocation of resources, provide incentives that stimulate innovation and economic growth, reward merit, and consequently are conducive to the greatest good of the greatest number. For the market to work, state action that distorts prices and interferes with rewards to investors must be minimized; rather the local state needs to offer incentives to investors if it is to compete within the world system of cities. Within this ideological framework, policies to reduce inequality and provide advantages to minority groups hinder the workings of the market's invisible hand and cause the economy to perform at a suboptimal level. Under this governing principle, efficiency becomes the single criterion for evaluating public policy, and cost-benefit analysis becomes the tool for its realization.

The use of cost-benefit analysis to assess policy derives from philosophical utilitarianism. Its governing principle of maximizing the greatest good for the greatest number underlies the types of calculations generally used for choosing among policy alternatives. Despite its prevalence it has been strongly criticized for failing to take into account the impacts of policies on minorities and its blindness to questions of distribution (Rawls, 1971; Campbell and Marshall, 2002). Thus, to take the example of urban redevelopment programs, displacement of residents is justifiable if the majority benefits even marginally, regardless of the serious costs to those displaced. Further, it usually involves a quantification of benefits that is biased in favor of the already well-off. For instance, investment in commuter rail, if it adds to time savings by high-income individuals, will have a greater payoff than expenditures on buses for low-income people whose time has less monetary value. The counterargument is that justice as the yardstick for measuring public policy effectiveness does not negate efficiency as a goal but instead requires the policy maker to ask to what end efficiency applies. If a policy serves the goal of assisting the most disadvantaged without wasting resources, in line with Rawls's difference principle, then the policy is efficient even if it does not maximize an aggregate cost-benefit ratio.

Democracy, Diversity, Equity

Three main approaches to the issue of justice in the city characterize recent writing on the subject; the differences among them are primarily a matter of emphasis. Most prominent during the latter part of the twentieth century within planning theory is communicative rationality (Forester, 1993; Innes, 1995), sometimes referred to as the collaborative approach (Healey, 2006). Derived from Habermas's concept of communicative rationality, the emphasis here is on democratic decision making and represents a reaction to the high-handed technocratic methods underlying urban renewal programs. It is

assumed that the stronger the role of disadvantaged groups in policy decisions, the more redistributional will be the outcomes; thus, broad participation and deliberation should produce more just outcomes.

Communicative rationality starts with an abstract proposition. According to Patsy Healey (1996, p. 239):

> A communicative conception of rationality … replaces[s] that of the self-conscious autonomous subject using principles of logic and scientifically formulated empirical knowledge to guide actions. This new conception of reasoning is arrived at by an intersubjective effort at mutual understanding. This refocuses the practices of planning to enable purposes to be communicatively discovered.

Within communicative theory, the planner's primary function is to listen to people's stories and assist in forging a consensus among differing viewpoints. Rather than providing technocratic leadership, the planner is an experiential learner, at most providing information to participants but primarily being sensitive to points of convergence. Leadership consists not in bringing stakeholders around to a particular planning content but in getting people to agree and in assuring that, whatever the position of participants within the social–economic hierarchy, no group's interest will dominate. Among political scientists, this viewpoint is generally captured in the term deliberative democracy and assumes that through interaction participants will modify their ideas and reach a consensus.

Critics of this approach contend that initial conditions of inequality cause any consensual outcome that results in to reflect the interests of the most powerful (see Huxley and Yiftachel, 2000; Campbell and Marshall, 2006; Flyvbjerg, 1998). They consider that bringing about changes favoring relatively disadvantaged groups necessarily involves conflict (Purcell, 2009). In relation to the role of the planner, Fainstein (2010) asserts that planners whose aim is justice need to intervene in the planning process, calling for policies that favor low-income and minority groups. Further, she worries that democracy can lead to exclusionary practices, since a situation in which all social classes are proportionally represented will rarely occur. Even when representatives of the poor do participate, they may be co-opted or manipulated. She concedes, however, that planners have little independent power and will only succeed in improving the situation of the less powerful when they have political backing from either grassroots movements or progressive politicians.

The debate over how much importance to attach to democratic decision making as opposed to the differential impacts of policy boils down to a dispute over the importance of process versus outcome. For those who regard a process-centered approach as inadequate for obtaining justice, the problem is that it fails to take into account the unequal positions of the participants. In Nancy Fraser's words (1997, p. 79): "Liberal political theory assumes that it is possible to organize a democratic form of political life on the basis of socioeconomic and sociosexual structures that generate systemic inequalities."

Diversity

Among philosophers, Rawls has been criticized for his individualistic approach to society. The critique centers on his seeming obliviousness to group identity (Young, 1990) and his insensitivity to nonmaterial forms of discrimination (Honneth, 2003). According to this viewpoint, discrimination against groups defined by their color, cultural inheritance, or sexual preferences cannot simply be collapsed into a manifestation of material inequality. Young (1990) argues that social justice requires recognition of and respect for group differences. She calls for the rejection of an assimilationist model under which difference is eradicated but rather the assertion of a positive sense of group difference wherein the group defines itself rather than being defined by others.

Toward the end of the twentieth century, the concern among philosophers with recognition of the other converged with an emphasis among urbanists on diversity. As used by urbanists the term has a variety of meanings (Fainstein, 2010). Among urban designers it refers to mixing building types; among planners it denotes both mixed uses of land and social heterogeneity of residential buildings, neighborhoods, and public spaces. Jane Jacobs (1961) was particularly influential in her call for a physical heterogeneity that would promote a corresponding social mixing. She maintains that such diversity will prove beneficial not only for producing attractive cities but for making cities economically productive. Her reasoning anticipates the widely publicized argument of Richard Florida (2002) that diversity stimulates creativity and in turn economic growth.

A number of urban scholars regard the merit of diversity not in its promotion of economic growth but rather in enhancing the right to the city. Leonie Sandercock (1998) terms her ideal city 'Cosmopolis' and depicts a metropolis that gives people from a variety of ethnic and racial backgrounds equal rights to city space and "the pleasures of anonymity." Richard Sennett (1970, 1990), who long ago championed "*The Uses of Disorder*," similarly praises the benefits of difference and even of conflict. New urbanists, who both write about and actually design communities, aim to achieve social diversity through a variety of building types, while land-use planners call for inclusionary zoning that requires new development to provide for low-income housing.

The achievement of diversity, however, may militate against other values. Moving people against their will in order to produce diversity, as has occurred in American programs to replace public housing with mixed-income projects (Goetz, 2003), is contrary to democratic norms of self-determination. Furthermore, there is a tension between heterogeneity and community. According to Robert Putnam (2007, p. 137), "immigration and ethnic diversity tend to reduce social solidarity and social capital. New evidence from the US suggests that in ethnically diverse neighbourhoods residents of all races tend to 'hunker down'. Trust (even of one's own race) is lower, altruism and community cooperation rarer, friends fewer." Iris Young supports neighborhood homogeneity within a metropolitan context of porous borders and multiple groups because of the need to recognize difference and to understand that living among those like oneself provides existential security (Young, 2000).

Equity

Edward Soja (2010) has highlighted the concept of uneven development in his investigation of spatial justice. Like Iris

Marion Young and David Harvey he begins with a depiction of injustice and considers that geography is "a significant causal force in explaining [inequitable] social relations and societal development" (2010, p. 63). He argues that the pursuit of justice requires gaining control over the processes producing unjust urban geographies. He does not identify specific programs to reduce spatial injustice but rather looks to coalitions of groups demanding the right to the city as the vehicles for achieving both greater material equity and also greater respect for marginalized populations. He describes such coalition building in Los Angeles and also the teaching of spatial justice practice at the University of California at Los Angeles as strategies for reaching a more just city.

Fainstein (2010) points out that the values of equity, diversity, and democracy may be in conflict, and she gives equity priority among them. She is particularly concerned with planning and redevelopment decisions made at the city level, and she examines them through an investigation of the cases of New York, London, and Amsterdam. She concludes that Amsterdam is the most equitable and democratic of the three and that New York has been most successful in absorbing immigrants. London is an intermediate case in regard to equity. Johannes Novy and Margit Mayer (2009, p. 104), however, criticize Fainstein for holding up the social democratic cities of Europe as a model, contending that it "distracts from and, worse, naturalizes the inequalities and injustices which mark them … ."

The ultimate intent of Fainstein's book is to specify policies that would benefit relatively disadvantaged social groups, as defined by income or marginality. To this end, she lists programs that enhance equity, stressing housing development for low-income households, preventing involuntary displacement, giving priority in economic development programs to the interests of employees and small businesses, and lowering intraurban transit fares. In furtherance of diversity, she calls for ending discriminatory zoning, insuring that boundaries between districts remain porous, providing widely accessible and varied public space, and mixing land uses. In regard to democracy, she calls for the use of advocates to represent groups that do not participate directly in decision making, consultation of target populations in areas to be redeveloped, and broad consultation for areas that are not yet developed but are under development pressure. She notes, however, that, if the aim is justice, the purpose of inclusion in decision making is to have interests fairly represented, not to value participation in and of itself. This further value may well underlie a vision of the good city, but it is not necessary for her definition of justice.

An important difference between her and David Harvey is that she is willing to embrace reform through existing political–economic processes rather than viewing greater justice as unattainable under capitalism. In Harvey's view, her approach "is thus constrained to mitigating the worst outcomes at the margins of an unjust system" (Harvey and Potter, 2009, p. 46). He calls capitalist liberal democracy a régime of rights and asserts: "My objection to this régime of rights is quite simple: to accept it is to accept that we have no alternative except to live under a régime of endless capital accumulation and economic growth no matter what the social, ecological, or political consequences" (Harvey and Potter, 2009, p. 43).

At the root of their disagreement is the question of whether or not the capitalist state within a political democracy can be an instrument for redistribution. Harvey, in line with Marx's dismissal of the capitalist state as the executive committee of the bourgeoisie, expects little from it. Furthermore, consonant with Marx's emphasis on production rather than distribution as the basis for inequality, he looks to restructuring the relations of production and the processes of spatial development rather than to enlarging the state's role in providing a social wage as key to creating "the city of one's heart's desire" (2009, p. 40). For Harvey, to begin with a prescription for policy outcomes rather than with a strategy for transforming power relations is a losing proposition.

It is not within the power of municipal governments to achieve transformational change. Only the nation state has this kind of leverage, and the more egalitarian cities of Europe admired by Fainstein are in fact underpinned by strong national welfare programs. At the same time, local policies make life better or worse for people. There are many decisions, especially involving housing and transport, made at the local level that differentially affect people's quality of life. The extent to which these decisions have responded to the needs of the relatively disadvantaged has been the result of local political pressures and the ways in which problems are framed. The hope underlying the discussion of the just city is that it can change the rhetoric around urban policy from a single-minded focus on competitiveness to a discourse about justice.
